General Information. IR spectra were collected on a Nicolet IR200 attenuated total reflectance FT-IR spectrometer. NMR spectra were recorded on a Bruker 400 MHz FT-NMR spectrometer. Chemical shifts are reported in parts per million (ppm) downfield from tetramethylsilane (TMS) with reference to internal solvent for 1H NMR and 13C NMR spectra. Multiplicities are abbreviated as follows: singlet (s), doublet (d), triplet (t), quartet (q), quintet (quint), septet (sept), multiplet (m), and broad (br). Optical rotations were taken on a Jasco P-1010 polarimeter with a wavelength of 589 nm. The concentration “c” has units of g/100 mL (or 10 mg/mL) unless otherwise noted. Analytical thin-layer chromatography (TLC) was performed using silica gel 60 F254 precoated plates (0.25 mm thickness) with a fluorescent indicator. Visualization was performed with standard potassium permanganate stain (10 g KMnO4, 20 g Na2CO3, 1 L water), standard p-anisaldehyde stain (23 mL p-anisaldehyde in 500 mL 95% EtOH, cooled to 0 °C, added 9.4 mL cold glacial AcOH and 31.3 mL conc. H2SO4, diluted to 1 L with 95% EtOH) or UV light. Flash column chromatography of organic compounds was performed using silica gel 60 (230-400 mesh). All enantiomeric purities were determined by chiral GC (Chiraldex G-TA) or chiral SFC (supercritical CO2, ADH column, 214 nm UV detection) and were compared to racemic samples.

All glassware was flame dried, and reactions were done under an atmosphere of argon unless otherwise noted. All organic solvents were dried by passage through solvent purification columns containing activated alumina and activated copper (the latter was used for solvents with no heteroatoms). All commercial chemicals were used as obtained. Compounds 2, 11, and 12 were synthesized and purified as reported.1

Rationale for Structural Assignment of Compound 19.

Using the $^1$H NMR, COSY, and NOESY spectra of 19, the aliphatic hydrogen atoms in the $^1$H NMR spectrum were assigned as shown on page S18. The chemical shift values, the splitting patterns in the $^1$H NMR spectrum and the coupling (both J values and COSY data) support the placement of the hydrogen atoms on the carbon skeleton. The NOESY spectrum was used to gain further insight. Diastereotopic $H_a$ and $H_a'$ were not differentiated. The diastereotopic $H_d$ and $H_d'$ were assigned based on a through-space interaction in the NOESY (which is not observed in the COSY) between the doublet of doublets at 4.21 ppm (the axial $H_d'$) and the quartet at 3.49 ppm ($H_b$). That interaction also supports the proposed bicyclic structure. The equatorial methyl groups were tentatively assigned based on a NOESY crosspeak between the doublet at 1.01 ppm ($H_i$) and the singlet at 1.23 ppm ($H_c$), leaving $H_g$ as the singlet at 1.43 ppm. As further support of the bicyclic structure and support for the stereochemistry of the carbon bearing the benzylxy group, there is a crosspeak in the NOESY spectrum between the singlet at 4.33 ppm ($H_b$) and the doublet at 1.01 ppm ($H_i$). This crosspeak is not present in the COSY spectrum.

As an alternative to the proposed Payne-rearrangement/epoxide opening sequence yielding 19, the reaction of 10 with aqueous sodium hydroxide could occur as shown in Scheme S1 to afford compound 31. This process is similar to the proposed mechanism for the formation of compound 23 but under basic conditions. The possibility of this reaction and therefore the formation of 31 instead of 19 was presented by a reviewer of the original manuscript. The author thanks the reviewer for their important discussion, observations, and contribution to this work and presents the following data in support of the product of the reaction of 10 with NaOH as 19.

The two differences between 31 and 19 are the absolute stereochemistry of the 2,6-dioxabicyclo[3.2.1]octane ring and the stereochemistry at the carbon bearing the benzylxy group. The absolute stereochemistry is not relevant in this case because 19 was made as a racemate, so the only difference between them is the stereochemistry at the carbon bearing the benzylxy group. The NOESY crosspeak mentioned above between $H_i$ and $H_i$ support the structure of the reaction of 10 and NaOH as 19, but ideally compound 31 could be formed and structurally characterized to differentiate 19 and 31.

Because compound 31 is structurally identical to 23 but in a lower oxidation state, compound 10 was treated with $p$-toluenesulfonic acid in benzene at room temperature to form 31 (the same way 23 was synthesized). A $^1$H NMR
The spectrum (DMSO-d$_6$) of the purified material showed a 4:1 ratio of a new compound (proposed structure 31) to 19. This spectrum was compared to a spectrum of 19 in DMSO-d$_6$, and the remaining peaks were assigned to 31 using the $^1$H NMR, COSY, and NOESY spectra (see page S32). In DMSO-d$_6$, the alcohol hydrogen atom appears as a doublet at 5.09 ppm (H$_d$), and there is a crosspeak in the NOESY indicating a through-space interaction with the singlet at 3.60 ppm (H$_b$). This is consistent with an axial hydrogen atom on the carbon bearing the benzyloxy group as shown in 31. The bicyclic structure of 31 is supported by a crosspeak between H$_h$ and H$_r$. These data support the structure of the major product of the reaction of 10 with p-TsOH to be 31, which in turn supports the proposition that the product formed by the treatment of 10 with NaOH is not 31.

8-(Benzyloxy)-1,5,7-trimethyl-2,6-dioxabicyclo[3.2.1]octan-4-ol (31). To a solution of racemic 10 (20 mg, 0.072 mmol) in 1 mL of benzene was added p-toluenesulfonic acid (5.5 mg, 0.029 mmol). After 2 h at room temperature the reaction was diluted with 2 mL of water and was extracted with 3 x 2 mL of ethyl acetate. The organic layers were combined, dried over sodium sulfate, and evaporated to an oil. The oil was purified by flash chromatography (45% ethyl acetate in hexanes) to afford 15 mg (75% total yield) of a 4:1 mixture of 31:19 as a colorless oil. R$_f$ = 0.31, 45% ethyl acetate in hexanes.
