We demonstrate single-mode lasing at telecommunication wavelengths from a circular nanocavity employing a radial Bragg reflector. Ultrasmall modal volumes and submilliwatt pump thresholds level are observed for lasers with InGaAsP quantum well active membrane. The electromagnetic field is shown to be tightly confined within the 300 nm central pillar of the cavity. The quality factors of the resonator modal fields are estimated to be on the order of a few thousands. © 2005 American Institute of Physics. [DOI: 10.1063/1.1947375]

The quest for the ultimate localization of light has been one of the central directions in contemporary research in many fields, such as integrated optics, quantum communication and computation, sensing, and more.1–3 Optical nanocavities with high-quality factors (Q) and small modal volume (V_{mode}) are key elements for a wide variety of applications, such as functional building blocks for integrated optical circuits, lasers, optical traps, and optical logic.4,5

In the past few years, much attention was focused on decreasing the modal volume and improving the Q of photonic crystal (PC) defect cavities by carefully optimizing the position, dimensions, and shape of the holes composing the crystal.6–9 This optimization procedure attempts to tune the effective length of the cavity to the maximal reflection frequency of the PC reflector and is generally conducted numerically. The main disadvantage of this process is the enormous number of parameters to be optimized and the endless number of configurations that potentially need to be considered.

Recently, we have proposed and demonstrated a novel class of circular resonators that are based on optimally designed radial Bragg reflectors.9–11 These devices, known as annular Bragg resonators (ABRs), are designed to support azimuthally propagating modes, with energy concentrated within a radial defect region or in a central pillar by radial Bragg reflection. Compared to conventional resonators based on total-internal reflection (TIR), the employment of the Bragg reflection mechanism offers improved control over the resonator parameters (Q, V_{mode}, etc.) and allows for engineering unique mode profiles. Compared to PC defect resonators, the radial symmetry of ABRs allows for analytical engineering the Bragg reflector for optimized Q and smaller modal volume. These properties make the ABR structure highly suitable for realizing ultracompact cavities, especially if they are designed for the mode with angular modal number m = 0. The m=0 mode is an interesting solution of a disk Bragg resonator consisting of a disk surrounded by a radial Bragg stack (see Fig. 1). Unlike other solutions with nonzero angular modal numbers, the m=0 mode is nondegenerate and features maximum intensity at the center of the device. This mode cannot be supported in conventional cavities because the propagation direction of the waves is perpendicular to the cavity interfaces.

In this letter, we report on the observation of single mode lasing from a Bragg-based disk nanocavity with ultrasmall modal volume, realized in active semiconductor material. Figure 1 depicts a scanning electron microscope (SEM) image of the nanocavity which was designed to resonate in the m=0 angular mode. The internal disk can be

FIG. 1. SEM image of the circular Bragg nanocavity designed to support the m=0 mode in the 300 nm wide central pillar.
viewed as the cavity while the concentric rings form the radial Bragg reflector, both designed to efficiently confine the specific mode in the cavity. The radius of the optimized nanocavity for telecommunication wavelengths is approximately 150 nm.

For a circular cavity to support a radial mode with an angular propagation coefficient of \( m \), the radius of the inner disk, \( \rho_0 \), and the grating profile \( \Delta \varepsilon \) must satisfy:

\[
\Delta \varepsilon (\rho) = \begin{cases} 
-2|\alpha| & \text{sin}(2 \text{ phase}(H_m^{(1)}(k_0 n_{\text{eff}} \rho))) < 0 \\
0 & \text{sin}(2 \text{ phase}(H_m^{(1)}(k_0 n_{\text{eff}} \rho))) \geq 0 
\end{cases}, \quad J_m(k_0 n_{\text{eff}} \rho_0) = 0, \tag{1}
\]

where \( k_0 \), \( n_{\text{eff}} \), and \( \alpha \) are, respectively, the desired resonance wave number, the slab effective index and the perturbation strength. \( H_m \) and \( J_m \) are, respectively, the Hankel and the Bessel functions of order \( m \). The widths of the resulting layers are determined by the zeros and extrema of the Bessel function of order \( m \). Due to the cylindrical geometry, the optimal layer widths required to confine the light in the central pillar are not constant\(^9,11,12\) but rather monotonically decreasing with the radial distance. The chirped nature of the gratings, which can be clearly seen in Fig. 1, is highly important. Deviation from that profile will result in nonoptimal phase relations between the partially reflected waves from the Bragg layers, and thus, in weaker confinement of the electromagnetic field. It should be noted that the realized grating profile shown in Fig. 1 is of “second-Bragg order” in the sense that the second term in the Fourier expansion of the grating is the term responsible for the radial reflection. Such an approach induces efficient vertical emission from the device which decreases the overall \( Q \) on one hand but enables simple observation of the intensity pattern evolving in the device on the other. The condition on the radius of the pillar can be intuitively understood when the optimized distributed reflector is considered effectively as a perfect mirror at the resonant Bragg \( k \) vector.\(^7\) The modal field profile of the device is given by a Bessel function of order \( m \) in the central pillar and an exponentially decaying Bessel function in the grating area where the decay constant, \( k \), is determined by the perturbation strength \( \alpha \) according to \( k = \alpha / 2n_0^2 \).

The nanocavity was fabricated within a 250 nm thick membrane of InGaAsP with six 75 Å quantum wells (QW) positioned at the center. After the resonator pattern was etched into the active material, the original InP substrate was removed and the membrane was transferred to a sapphire plate using an ultraviolet curable optical adhesive to improve the vertical confinement of the electromagnetic field in the device. A detailed description of the fabrication process is given in Ref. 13. The effective index of the membrane was found to be approximately 2.8 for the \( H_z \) polarization and 2.09 for the \( E_z \) polarization. Since the \( H_z \) polarization is more confined than the \( E_z \) polarization and the optical gain of the compressively strained QW structure used favors the \( H_z \) polarization,\(^14\) we optimized the radial structure to this polarization.

The emitted spectrum and the near-field (NF) intensity pattern of the nanocavity were examined at room temperature under pulsed optical pumping using a mode-locked Ti:Sapphire laser operating at 890 nm. The pump beam was focused through the transparent sapphire substrate on the back side of the sample with a 50× objective lens. The position of this lens was used to control the size and the posi-

We attribute these modes to emission from the external...in principle using a spherical Bragg cavity or a metallic cubic half-

Theoretical limit of modal volume can be achieved...and DARPA.

In conclusion, we demonstrated single-mode lasing at telecommunications wavelengths from a circular Bragg nanolaser with an ultrasmall modal volume. Lasing was achieved at room temperature under pulsed optical pumping conditions at sub-mW threshold levels. Such cavities can easily be integrated with other photonic devices such as PC waveguides and distributed feedback lasers to realize compact and highly functional optical circuits.
