(Received 4 November 2002; published 15 April 2003)

We study the string modes in \( pp \)-wave light-cone string field theory. First, we clarify the discrepancy between the Neumann coefficients for the supergravity vertex and the zero mode of the full string one. We also repeat our previous manipulation of the prefactor for the string modes and find that the prefactor reduces to the energy difference of the cos modes minus that of the sin modes. Finally, we discuss impurity number nonpreserving three-string processes.

I. INTRODUCTION

String theory on a \( pp \)-wave background and \( N = 4 \) super Yang-Mills (SYM) gauge theory restricted to a large \( \Lambda \) charge were proposed to be dual in Ref. [1]. This proposal was partly motivated by the fact that \( pp \)-wave background can be obtained by taking the Penrose limit of anti–de Sitter (AdS) space [2]. The explicit comparison is made possible because string theory on the \( pp \)-wave background can be solved [3,4] despite the fact that a nonzero Ramond-Ramond (RR) flux exists. The anomalous dimension of certain gauge theory operators have been computed in Refs. [5–8] and shown to agree with the light-cone energy of the dual string states. As for the string interaction part, the explicit proposal of the correspondence between the string theory and the gauge theory quantities [7]

\[
\frac{1}{2} \langle 2 | \langle 3 | H = \mu (\Delta_1 + \Delta_2 - \Delta_3) C_{123},
\] (1.1)

follows from unitarity check for large \( \mu \). There have been many reports in the literature verifying this relation [9–15]. Despite the fact that all the tests for the on-shell three-point Hamiltonian matrix elements of scalar excitations have been successful, similar relation for vector excitations [16,17] or for four-point function [18] seems to avert a naive generalization.

We address three issues of the \( pp \)-wave light-cone string field theory constructed in [19]. First of all, it has been noted in the literature [10] that the supergravity Neumann matrices do not match the zero mode of the string Neumann matrices with \( \mu \to \infty \). In this paper, we resolve the origin of this discrepancy.

Second, role of the prefactor in the \( pp \)-wave light-cone string field theory was discussed in Refs. [7,9,13,14]. Through the unitary check, the contribution of the prefactor was proposed to be just an overall factor of difference in energy of incoming and outgoing string states. In [13], the prefactor was recast in a form to make this fact manifest. However, the analysis was restricted to the supergravity vertex. In Ref. [14], the Hamiltonian matrix elements including the full string prefactor were calculated as a whole and the proposal of Ref. [7] was confirmed to first order in \( \lambda' \), but the explicit evaluation was only restricted to two processes and the role of the prefactor was not identified. Here we would like to combine Refs. [13] and [14] and compare the prefactor for the full string vertex with a difference in energies of string states for any \( \mu \alpha' \rho \), using a factorization theorem of the Neumann coefficients shown in Refs. [20,21].

Third, let us make an attempt to extend the conjecture to impurity number nonpreserving processes explicitly. Impurity number nonpreserving processes are proposed [7] to correspond to nonperturbative effects in the gauge theory side. We shall show that the result of string theory cannot be reproduced only from the perturbative gauge theory. We consider, at the tree-level, impurity number non preserving process with two incoming states with \( m + 1 \) and \( n + 1 \) impurities and one outgoing state with \( m + n \) impurities. On the gauge theory side, it is known that the contribution is subleading in \( 1/\Lambda \) and vanishes in the \( pp \)-wave limit. However, on the string theory side the corresponding correlation function is proportional to \( \bar{N}^{(12)}(\bar{N}^{(13)})^m(\bar{N}^{(23)})^n \) and is nonvanishing. This is another sign that the proposal of Ref. [7] should be modified for more general string interactions.

In the following sections we shall address these questions. We clarify the discrepancy between the supergravity vertex and the string vertex in the following section. In Sec. III, we repeat the manipulation of the prefactor in our previous paper [13] for the full string vertex. We also discuss the impurity number nonconserving process in Sec. IV. Finally we conclude.

II. SUPERGRAVITY VERTEX

In this section, we shall clarify the discrepancy between the supergravity vertex and the zero modes of the string vertex. In this paper, we mainly adopt the notation of Refs. [19,14,22]. Only in this section we set \( \alpha^{(3)} = -1 \) instead of introducing \( \beta \) or \( \gamma \) for simplicity. In the final result, \( \alpha^{(3)} \) can be restored on dimensional grounds. The Neumann coefficients for the bosonic modes are given as

\[
\bar{N}^{(rs)} = \delta_{rs} 1 - 2 \sqrt{C(s)} X^{(r)} X^{(s)} \frac{1}{\Gamma_a} \sqrt{C(s)},
\] (2.1)

"Email address: pether@theory.caltech.edu
† Email address: moriyama@theory.caltech.edu
‡ Email address: jongwon@theory.caltech.edu"
with the matrix $\Gamma_a$, where

$$\Gamma_a = \sum_{r=1}^{3} X^{(r)} C_r X^{(r)\top}. \tag{2.2}$$

Here $X^{(r)}$ denote infinite matrices of the Fourier expansion for the third string in terms of the other two with their indices running over the set of all integers. If we set $X^{(1)}=1$, then $X^{(r)} (r=1,2)$ can be expressed as $(r,s=1,2, \epsilon_{12}^2=1)$

\[
\begin{pmatrix}
0 & 0 \\
1 & 0 \\
-(e^{r \alpha_1} / \sqrt{2}) \sqrt{C B} & \sqrt{C A^{(r)} \sqrt{C}^{-1}}
\end{pmatrix}, \tag{2.3}
\]

with three rows (columns) representing the negative modes, the zero mode, and the positive modes, respectively, and $A_{mn}^{(r)}$, $B_m$, $C_{mn}$, and $C_{(r)mn}$ are given by

$$A_{mn}^{(1)} = (-1)^{m+n} \frac{2}{\pi} \frac{\sin m \alpha_1 \sin n \alpha_1}{m^2+n^2 \alpha_1^2}, \tag{2.4}$$

$$A_{mn}^{(2)} = (-1)^{m+n} \frac{2}{\pi} \frac{\sin m \alpha_2 \sin n \alpha_2}{m^2+n^2 \alpha_2^2}, \tag{2.5}$$

$$B_m = (-1)^{m+1} \frac{2}{\pi} \frac{\sin m \alpha_1}{m \sqrt{\alpha_1^2 (1+\epsilon_1^2)}}, \tag{2.6}$$

$$C_{mn} = \delta_{mn} \omega_r, \quad C_{(r)mn} = \delta_{mn} \omega_r, \quad r=1,2,3, \tag{2.7}$$

with $\omega_r \equiv \sqrt{(\mu \alpha_r)^2+m^2}$ for $r=1,2$ and $\omega_3 = \sqrt{\mu^2+m^2}$.

If we take the large $\mu$ limit for the zero mode of the Neumann coefficient matrices $\bar{N}_{00}^{(rs)}$, we find that

$$\bar{N}_{00}^{(rs)} = \begin{pmatrix} 0 & 0 & -\sqrt{\alpha_1} \\ 0 & 0 & -\sqrt{\alpha_2} \\ -\sqrt{\alpha_1} & -\sqrt{\alpha_2} & 0 \end{pmatrix}. \tag{2.8}$$

Clearly, they do not agree with the supergravity vertex $M^{rs}$

$$M^{rs} = \begin{pmatrix} \alpha_2 & -\sqrt{\alpha_1 \alpha_2} & -\sqrt{\alpha_1} \\ -\sqrt{\alpha_1 \alpha_2} & \alpha_1 & -\sqrt{\alpha_2} \\ -\sqrt{\alpha_1} & -\sqrt{\alpha_2} & 0 \end{pmatrix}. \tag{2.9}$$

In the construction of the supergravity vertex, the dependence of $\mu$ does not appear explicitly in the Neumann coefficient matrices $M^{rs}$, so one might regard this mismatch as a puzzle. However, the supergravity vertex is constructed implicitly under the assumption that the zero modes decouple completely from the higher ones. This is not true, in general, because there are nonvanishing overlaps between the zero modes and the positive excited modes in the Fourier expansion matrices $X^{(r)}$. It is only in the flat space limit $\mu \to 0$ that the zero modes should decouple.

Let us demonstrate this observation more explicitly. Evaluating the matrix $\Gamma_a$, Eq. (2.2), by substituting the expression for $X^{(r)}$, Eq. (2.3), we find that the zero modes and the positive modes decouple as

$$\Gamma_a = \begin{pmatrix} \sqrt{C_1} & 0 & 0 \\ 0 & 2 \mu & 0 \\ 0 & 0 & \sqrt{C_2} \end{pmatrix}. \tag{2.10}$$

Using this expression, we find

$$\frac{\bar{N}_{00}^{(rs)}}{M^{rs}} = 1 - \mu \alpha_1 \alpha_2 B \Gamma_2^{-1} B = R, \tag{2.11}$$

for $r,s=1,2$, while $\bar{N}_{00}^{(rs)}/M^{rs} = 1$, for $r=3$ or $s=3$. From the above observation, we expect that $R \to 1$ as we take the flat space limit $\mu \to 0$, while $R \to 0$ as $\mu \to \infty$. Before proceeding to analytical computation illustrating this behavior, let us make a few comments.

The aforementioned dependence of $R$ on $\mu$ can be seen from the numerical analysis. In Table 1, we present a numerical result for $R$ with $\alpha_1(1)=1/\sqrt{2}$ and for various values of $\mu$. The reason we take $\alpha_1(1)=1/\sqrt{2}$ is purely technical; we can avoid treating the indefinite forms by adopting irrational number for $\alpha_1(1)$. Note that the second term of $R$ in Eq. (2.11) makes $R$ deviate from 1, and this term comes from the off-diagonal part of $X^{(r)}$. Since the off-diagonal part represents the overlap between the zero modes and the positive ones, this fact confirms the reason why the two Neumann matrices do not agree; supergravity modes do not decouple from the string modes in general.

Let us proceed with the analytical computation. The asymptotic behavior of $R$ in the limit $\mu \to \infty$ was evaluated in Refs. [20,22]. The result is

\footnote{Expression (2.11) and its behavior in the flat space limit $\mu \to 0$ were also discussed in Ref. [21].}

When one restricts to the bosonic excitation, only the third term in Eq. (3.2) contributes. In addition, from the structure of the gamma matrices [9,13], we know that except for a relative minus sign$^2$ between the two $SO(4)'s$, the gamma matrix reduces to a Kronecker delta. Hence, the prefactor is given explicitly as

$$\left( \sum_{r=1}^{3} \sum_{m=0}^{\infty} F^+(r,m)a^+_m(r) \right)^2 - \left( \sum_{r=1}^{3} \sum_{m=0}^{\infty} F^-(r,m)a^-_m(r) \right)^2.$$

On the other hand, the difference in energy is given by

$$P_1^+ + P_2^- - P_3^- = \sum_{r=1}^{3} \sum_{m=-\infty}^{\infty} (\omega(r,m)/\alpha(r))a^+_m(r)a^-_m(r).$$

Acting it on the bosonic vertex $E_a|\text{vac}\rangle$ gives

$$\left( P_1^+ + P_2^- - P_3^- \right) E_a|\text{vac}\rangle = \sum_{r,s=1}^{3} \sum_{m,n=0}^{\infty} a^+_m(r)a^-_n(s)N_{mn}^{(r,s)}E_a|\text{vac}\rangle$$

$$+ \sum_{r,s=1}^{3} \sum_{m,n=1}^{\infty} a^+_m(r)a^-_n(s)\omega(r,m)/\alpha(r)$$

$$\times N_{m-n}^{(r,s)}a^+_n(s)E_a|\text{vac}\rangle.$$

Let us compare expression (3.5) with the prefactor (3.3). We first concentrate on the positive modes. For these modes, $F^+(r,m)$ is given as [14]

$$F^+(r,m) = \frac{1}{\sqrt{2}} \frac{\alpha}{\alpha(r)} \sqrt{CC(r)} U(r)^{-1} A(r)^T Y^{-1} B,$$

up to normalization$^3$ with

$$Y = \sum_{r=1}^{3} A(r)^{-1} A(r)^T, \quad U(r) = (C(r) - \mu \alpha(r))/C,$$

$^2$See also Ref. [17] for a recent proposal related to this relative minus sign.

$^3$In Ref. [14], the overall normalization of the prefactor was fixed by comparing with the supergravity vertex $M^T$ with $r,s = 1,2$. This normalization is reliable only when $\mu$ is small.
and the Neumann coefficients are shown to have the following useful factorization property [20,21]:

\[
\tilde{N}^{(rs)}_{mn} = -\frac{\alpha}{R} \frac{m\tilde{N}^{(r)}_m \tilde{N}^{(s)}_n}{\alpha(r) \omega_{m(r)} + \alpha(s) \omega_{n(s)}},
\]

with

\[
\tilde{N}^{(r)}_m = -\sqrt{\frac{C(r)}{C}} U_{(r)}^{-1} A_{(r)}^\dagger \Gamma^+_{m} B.
\]

Since we can also show the property \(Y^{-1}B=\Gamma^+_{m}B/R\) [20,21], \(\tilde{N}^{(r)}_m\) is closely related to \(F^{(r)}_{(m)}\). In fact, we can rewrite the factorization theorem (3.8) in terms of \(F^{(r)}_m\) as

\[
\tilde{N}^{(rs)}_{mn} = -\frac{R}{\alpha} \frac{2}{\omega_{m(r)}/\alpha(r) + \omega_{n(s)}/\alpha(s)} F^+_m F^+_n.
\]

Although the expression for \(F^+_m\), Eq. (3.6), and the factorization theorem (3.8) were originally obtained for the positive modes, one can show that the present formula (3.10) holds also for the zero mode if the indefinite from of \(\tilde{N}^{(23)}_{00}\) and \(\tilde{N}^{(23)}_{00}\) is interpreted properly. Substituting this factorization theorem (3.10) into the energy difference (3.5) and exchanging the dummy labels \((r,m)\) and \((s,n)\), we find

\[
\sum_{r,s=1}^{3} \sum_{m,n=0}^{\infty} a^\dagger_{m(r)}(\omega_{m(r)}/\alpha(r))\tilde{N}^{(rs)}_{mn} \alpha(s) E_{a} |\text{vac}\rangle = -\frac{R}{\alpha} \left( \sum_{r,s=1}^{3} \sum_{m,n=0}^{\infty} F^+_m a^\dagger_{m(r)} \right)^2 E_{a} |\text{vac}\rangle.
\]

We can also repeat the above calculation for the negative modes by noting\(^4\) [14]

\[
\tilde{N}^{(rs)}_{-m-n} = -(U_{(r)} \tilde{N}^{(r)}_{-m}) U_{(s)} = \sum_{m,n=0}^{\infty} a^\dagger_{m(r)}(\omega_{m(r)}/\alpha(r)) \tilde{N}^{(rs)}_{mn} a^\ast_{n(s)} E_{a} |\text{vac}\rangle,
\]

Using these formulas, the Neumann coefficient matrices for the negative modes can be expressed as

\[
\tilde{N}^{(rs)}_{-m-n} = -\frac{R}{\alpha} \frac{2}{\omega_{m(r)}/\alpha(r) + \omega_{n(s)}/\alpha(s)} F^+_m F^+_n.
\]

Therefore, the contribution from the negative modes gives

\[\sum_{r,s=1}^{3} \sum_{m,n=1}^{\infty} a^\dagger_{-m(r)}(\omega_{m(r)}/\alpha(r)) \tilde{N}^{(rs)}_{-m-n} a^\dagger_{-n(r)} E_{a} |\text{vac}\rangle.
\]

Consequently, the prefactor does not reduce to the energy difference, but reduces to the energy difference of the non-negative \((cos)\) modes minus that of the negative \((sin)\) modes:

\[(\text{Prefactor}) \sim \left( P^+_1 + P^+_2 - P^+_3 \right) |cos - (P^+_1 + P^+_2 - P^+_3) |sin.
\]

We note that this rewriting holds for any value of \(\mu\), including the flat space limit. Also, the prefactor is diagonal only in the \(cos/sin\) basis, and not in the \(exp\) basis, which is natural in the context of the \(pp\)-wave/\(SYM\) correspondence. Here \(\sim\) means that this relation holds up to some scalar factor, because the normalization of the prefactor is still unknown. As we pointed out in the footnote of Eq. (3.6), in Ref. [14] the normalization of the prefactor was determined by comparing with the supergravity vertex \(M^{rs} (r,s = 1,2)\) and this normalization is reliable only for small \(\mu\). Therefore, the overall normalization should be fixed in another way. For example, if we simply replace \(M^{rs}\) by the zero modes of the string Neumann matrices \(\tilde{N}^{(rs)}_{00} = M^{rs} R\) when fixing the normalization, then the scalar factor no longer depends on \(\mu\) but only on some numbers and \(\alpha\). To be more precise, it is necessary to determine the overall scalar factor completely without mentioning to the supergravity vertex. This issue of overall normalization constant can be circumvented by computing ratio of three-point functions as done in Refs. [10,11].

**IV. TOWARDS IMPURITY NUMBER NONPRESERVING PROCESS**

Having acquired a systematic viewpoint of the prefactor, let us proceed by checking if the string/gauge correspondence holds beyond the impurity number conserving processes. We shall consider the process\(^5\) with two incoming states with \(m+1\) and \(n+1\) impurities and one outgoing state with \(m+n\) impurities. Here, we shall restrict ourselves to the zero modes and abbreviate \(\tilde{N}^{(r)}_{rs}\) as \(\tilde{N}_{rs}\). First of all, let us consider the string theory side. Using [13] and the argument of Sec. III, all we have to do is to calculate the following quantity:

\[\langle O_{n}^{a_1 a_2^{a_1+n} a_3^{m+n}}\rangle,
\]

with \(\langle O\rangle\) defined as

\[\langle O\rangle = \langle \text{vac} | O E_{a} |\text{vac}\rangle.
\]

Since \(\tilde{N}_{13} = 0\), \(a_2\) cannot be contracted with itself. Therefore, we have three types of terms: \(\tilde{N}_{11} \tilde{N}_{m+1} \tilde{N}_{n+1}^{m+n} = 0\),

\[\sum_{r,s=1}^{3} \sum_{m,n=0}^{\infty} a^\dagger_{-m(r)}(\omega_{m(r)}/\alpha(r)) \tilde{N}^{(rs)}_{-m-n} a^\dagger_{-n(r)} E_{a} |\text{vac}\rangle.
\]

\[^4\]We are grateful to A. Pankiewicz for informing us that Eq. (3.13) in the original version, which was first obtained in Ref. [14], should be corrected by an extra factor \(i\).

\[^5\]Typical scaling of similar amplitudes in large \(\mu\) limit was also discussed in Ref. [14].
To summarize, the correctly normalized matrix element is given as

\[
\mathcal{N}_{22} \mathcal{N}_{13} \mathcal{N}_{23}^{-1}, \quad \text{and} \quad \mathcal{N}_{12} \mathcal{N}_{13} \mathcal{N}_{23}^n. \]

The combinatorial coefficient of \( \mathcal{N}_{12} \mathcal{N}_{13} \mathcal{N}_{23}^{-1} \mathcal{N}_{23}^n \) is obtained as follows. First of all, since \( a_2 \) is always contracted with \( a_3 \), we have \((m+n)(m+n-1) \ldots m \) ways to do this. The rest of \( a_3 \) have to be contracted with \( a_1 \), and there are \((m+1)m \ldots 3 \) ways to do this. Finally, the remaining two \( a_1 \)'s have to be contracted by themselves uniquely. Therefore, the coefficient of \( \mathcal{N}_{12} \mathcal{N}_{13} \mathcal{N}_{23}^{-1} \mathcal{N}_{23}^n \) is given as

\[
(m+n)(m+n-1) \ldots m \cdot (m+1)m \ldots 3 \cdot 1
\]

\[
= \frac{(m+1)m}{2} (m+n)!. \quad (4.3)
\]

Similar reasoning yields the coefficient of \( \mathcal{N}_{22} \mathcal{N}_{13} \mathcal{N}_{23}^{-1} \mathcal{N}_{23}^n \) to be

\[
(m+n)(m+n-1) \ldots n \cdot (n+1)n \ldots 3 \cdot 1
\]

\[
= \frac{(n+1)n}{2} (m+n)!. \quad (4.4)
\]

The coefficient of \( \mathcal{N}_{12} \mathcal{N}_{13} \mathcal{N}_{23}^n \) can be computed by subtracting the previous two cases from the combinatoric factor of contracting all \( a_3 \) with \( a_1 \) or \( a_2 \). The coefficient of \( \mathcal{N}_{12} \mathcal{N}_{13} \mathcal{N}_{23}^n \) is found to be

\[
(m+n+2)(m+n+1) \ldots 3 - \frac{(m+1)m}{2} (m+n)! - \frac{(n+1)n}{2} (m+n)! = (m+1)(n+1)(m+n)!. \quad (4.5)
\]

To summarize, the correctly normalized matrix element is given as

\[
\left( \begin{array}{ccc}
a_1^{m+1} & a_2^{n+1} & a_3^{m+n} \\
\sqrt{(m+1)!} & \sqrt{(n+1)!} & \sqrt{(m+n)!} \end{array} \right) = \frac{(m+n)!}{\sqrt{(m+1)!}(n+1)!/(m+n)!} \left( \frac{(m+1)m}{2} \mathcal{N}_{12} \mathcal{N}_{13} \mathcal{N}_{23}^{-1} \mathcal{N}_{23}^n + \frac{(n+1)n}{2} \mathcal{N}_{22} \mathcal{N}_{13} \mathcal{N}_{23}^{-1} \mathcal{N}_{23}^n + (m+1)(n+1) \mathcal{N}_{12} \mathcal{N}_{13} \mathcal{N}_{23}^{-1} \mathcal{N}_{23}^n \right). \quad (4.6)
\]

Now let us turn to the gauge theory side. At the tree level, we have

\[
\langle \mathcal{O}^J_{0,0}(m+1) \mathcal{O}^J_{0,0}(n+1) \mathcal{O}^J_{0,0}(m+n) \rangle = \frac{1}{\mathcal{N}_{J,m+n} \mathcal{N}_{J_2,n+1} \mathcal{N}_{J_1,m+1}} \frac{1}{J_1!m! J_2!n!} \left( J_1 + m \right) \left( J_2 + n \right)!, \quad (4.7)
\]

with \( \mathcal{N}_{J,n} = \sqrt{N^{j+n}(J+n-1)!/(J!n)!} \). To compare this result with that of the string theory side, we have to take the \( pp \)-wave limit: \( J, N \to \infty \) with \( J^2/N \) fixed. In this limit, the ratio to the vacuum three-point function is given by

\[
\frac{\langle \mathcal{O}^J_{0,0}(m+1) \mathcal{O}^J_{0,0}(n+1) \mathcal{O}^J_{0,0}(m+n) \rangle}{\langle \mathcal{O}^J \mathcal{O}^J \mathcal{O}^J \rangle} \to \sqrt{(m+1)(n+1)} \sqrt{m+n!} J \left( \frac{J_1}{J} \right)^{(m-1)/2} \left( \frac{J_2}{J} \right)^{(n-1)/2}. \quad (4.8)
\]

Therefore, in the \( pp \)-wave limit the perturbative field theory results simply vanish at the tree level. Next order in perturbation theory would give a contribution of order \( \lambda \), but due to the usual nonrenormalization theorem for two and three point functions of chiral primary operators \([24,25]\), we do not expect any perturbative corrections to the above amplitudes.

From the analysis done in Sec. II, we know that \( \mathcal{N}_{ss} \) scales as \( 1/\mu \) for large \( \mu \) for \( r, s = 1.2 \). Hence, the string amplitude scales as half-integer power of the effective coupling \( \lambda' \) at small \( \lambda' \). It seems difficult to reproduce this behavior in the perturbative gauge theory, and in order to reproduce the string theory results, we need to include nonperturbative effects as well \([14,22]\). The similarity between the coefficient of Eq. (4.8) and that of the last term of Eq. (4.6) might be a clue for resolving this mismatch.

\[\text{V. Conclusion}\]

In this paper, we have reexamined the \( pp \)-wave light-cone string field theory. In doing so, we resolved the apparent puzzle regarding the mismatch between supergravity Neumann matrices and the fully string ones. The mismatch is shown to be due to the overlap of the zero modes with the excited ones. The match is of course restored in the flat space limit \( \mu = 0 \). Following this, we concluded that the full string prefactor does not reduce to the difference in energy between the incoming and outgoing string states. Instead, it reduces to the energy difference of the non-negative (cos) modes minus that of the negative (sin) modes. Finally, we showed that the proposal of Ref. [7] does not naively generalize to the impurity number nonpreserving amplitudes. We expect that nonperturbative effects play an important role here.
Note added. After our submission of the present paper, we were informed by the author of Ref. [21] that the formula (3.13) in the original version of the present paper, which was first obtained in Ref. [14], should be corrected by an extra factor of $i$ on the right-hand side. Accordingly, Eqs. (3.14) and (3.15) also have to be corrected by a minus sign. Therefore, our original claim in Sec. III, that the prefactor reduces to the energy difference no longer holds. Instead, it reduces to the energy difference of the non-negative (cos) modes minus that of the negative (sin) modes. We have made corrections in Sec. III accordingly.
