Abstract. Column-averaged volume mixing ratios of carbon dioxide and methane retrieved from the Greenhouse gases Observing SATellite (GOSAT) Short-Wavelength InfraRed observation (GOSAT SWIR XCO2 and XCH4) were compared with the reference calibrated data obtained by ground-based high-resolution Fourier Transform Spectrometers (g-b FTSs) participating in the Total Carbon Column Observing Network (TCCON).

Preliminary results are as follows: the GOSAT SWIR XCO2 and XCH4 (Version 01.xx) are biased low by 8.85 ± 4.75 ppm (2.3 ± 1.2 %) and 20.4 ± 18.9 ppb (1.2 ± 1.1 %), respectively. The standard deviation of the GOSAT SWIR XCO2 and XCH4 is about 1 % (1σ) after correcting the negative biases of XCO2 and XCH4 by 8.85 ppm and 20.4 ppb, respectively. The latitudinal distributions of zonal means of the GOSAT SWIR XCO2 and XCH4 show similar features to those of the g-b FTS data except for the negative biases in the GOSAT data.

1 Introduction

The concentration of carbon dioxide (CO2) has increased from about 280 to 380 ppm over the past century due to the burning of fossil fuels associated with expanding industrial activities (IPCC, 2007). CO2 absorbs infrared radiation from the surface and hence an increase in CO2 concentrations leads to a rise in atmospheric temperature. CO2 and other trace gases such as methane (CH4), nitrous oxide (N2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs) and sulfur hexafluoride (SF6) are greenhouse gases that are subject to emissions regulations under the Kyoto Protocol. Together, CO2 and CH4 account for over 80 percent of the total anthropogenic warming effect caused by all greenhouse gases based on the estimates of radiative forcing from 1750 to 2005 (IPCC, 2007). Changes in temperature can cause feedbacks that alter CO2 concentrations by influencing the biosphere (Cox et al., 2000). Methane in the atmosphere is determined by a balance between emission from the surface and loss in the soils and by OH radicals in the atmosphere. After almost a decade of near-zero growth, globally-averaged atmospheric methane increased during 2007 and 2008. The cause of this increase is not yet clear (Dlugokencky et al., 2009). To accurately predict future atmospheric CO2 and CH4 concentrations and their impacts on climate, it is necessary to clarify the distribution and variations of those sources and sinks.
Current estimates of CO₂ flux from inverse methods rely mainly on ground-based data (Baker et al., 2006). Errors in the estimation of regional fluxes from Africa and South America are particularly large because ground-based monitoring stations are sparsely located in those regions. Spectroscopic remote sensing from space is capable of acquiring data that cover the globe and hence is expected to reduce errors in the CO₂ flux estimation using inverse modeling. To improve annual flux estimates on a sub-continental scale, the required precision of monthly averaged column-averaged volume mixing ratio of carbon dioxide ($X_{\text{CO}_2}$) is less than 1 % on a 8° × 10° grid without biases or with uniform biases (Rayner and O’Brien, 2001; Houweling et al., 2004; Miller et al., 2007). To reduce the uncertainty in monthly, sub-continental (about 500 km) methane source strengths from satellite measurements, the precision of the column-averaged volume mixing ratios of methane is required to be 1–2 % without systematic biases (Meirink et al., 2006). For this purpose, satellite-based data products must be validated by higher-precision data obtained independently using ground-based or aircraft measurements (Chahine et al., 2005; Sussmann et al., 2005; Dils et al., 2006; Schneising et al., 2008; Kulawik et al., 2010).

In this study, data products retrieved by the National Institute for Environmental Studies (NIES) from spectra obtained by the Greenhouse gases Observing SATellite (GOSAT) are compared with ground-based high-resolution Fourier Transform Spectrometer (g-b FTS) data calibrated to the World Meteorological Organization (WMO) scale. In Sect. 2, we present an overview of the GOSAT project, GOSAT instruments and observations, and retrievals from the GOSAT Thermal And Near-infrared Sensor for carbon Observation Fourier Transform Spectrometer, measuring in the Short-Wavelength InfraRed (TANSO-FTS SWIR). Reference data measured with g-b FTSs are described in Sect. 3. Characteristics of GOSAT SWIR products and preliminary results compared with the reference data are presented in Sect. 4, and the discussion and conclusions follow.

2 Overview of GOSAT, the GOSAT instruments, and data products retrieved from GOSAT TANSO-FTS SWIR observations

2.1 GOSAT

GOSAT, launched on 23 January 2009, is the world’s first satellite dedicated to measuring the atmospheric concentrations of CO₂ and CH₄ from space. The GOSAT Project is a joint effort of the Ministry of the Environment (MOE), the NIES, and the Japan Aerospace Exploration Agency (JAXA). NIES is responsible for (1) developing the retrieval of greenhouse gas concentrations (Level 2 products) from satellite and auxiliary data, (2) validating the retrieved greenhouse gas concentrations, and (3) producing higher-level processing such as monthly averaged $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$ (Level 3 products) and Level 4 carbon flux estimates. The primary purpose of the GOSAT is to make more accurate estimates of these fluxes on sub-continental scales (several hundred thousand square kilometers) and contributing toward the broader effort of environmental monitoring of ecosystem carbon balance. Further, through research using the GOSAT product, new knowledge will be accumulated on the global distribution of greenhouse gases and their temporal variations, as well as the global carbon cycle and its influence on climate. These new findings will be utilized to improve predictions of future climate change and its impacts.

2.2 GOSAT instruments and observation methods

Details of the GOSAT instruments have been described by Kuze et al. (2009). GOSAT is placed in a sun-synchronous orbit with an equator crossing time of about 13:00 local time, with an inclination angle of 98 degrees. GOSAT flies at an altitude of approximately 666 km and completes an orbit in about 100 min. The spacecraft returns to observe the same point on Earth every three days. The instruments onboard the satellite are TANSO-FTS and the TANSO Cloud and Aerosol Imager (TANSO-CAI).

TANSO-FTS has a Michelson interferometer that was custom designed and built by ABB-Bomem, Quebec, Canada. Spectra are obtained in four bands: band 1 spanning 0.758–0.775 µm (12 900–13 200 cm⁻¹) with 0.37 cm⁻¹ or better spectral resolution, and bands 2–4, spanning 1.56–1.72, 1.92–2.08, and 5.56–14.3 µm (5800–6400, 4800–5200, and 700–1800 cm⁻¹, respectively) with 0.26 cm⁻¹ or better spectral resolution. The TANSO-FTS instantaneous field of view is ~15.8 mrad corresponding to a nadir footprint diameter of about 10.5 km at sea level. The nominal single-scan data acquisition time is 4 s.

TANSO-FTS observes solar light reflected from the earth’s surface as well as the thermal radiance emitted from the atmosphere and the surface. The former (SWIR region) is observed in bands 1 to 3 of the FTS in the daytime only, and the latter (Thermal InfraRed, TIR, region) is captured in band 4 during both the day and the night. The surface reflection characteristics of land and water differ significantly. The land is close to Lambertian, whereas the ocean is much more specular. TANSO-FTS observes scattered sunlight over land using a nadir-viewing observation mode, and over ocean using a sunglint observation mode.

TANSO-CAI is a radiometer and observes the state of the atmosphere and the surface during daytime. The image data from CAI are used to determine cloud properties over an extended area that includes the FTS’ field of view as described by Ishida and Nakajima (2009). As part of the retrieval, cloud characteristics and aerosol amounts are also retrieved. This information can be used to reject cloudy scenes and correct the influence of aerosols on the retrieved $X_{\text{CO}_2}$ and $X_{\text{CH}_4}$.
Over the three-day orbital repeat period, TANSO-FTS takes several tens of thousands of observations that cover the globe. Since the retrievals are limited to areas under clear sky conditions, only about ten percent of the spectra obtained by TANSO-FTS can be used for the retrieval of CO\(_2\) and CH\(_4\). Nevertheless, the number of remaining data points far surpasses the current number of ground monitoring stations used for analysis in the World Data Centre for Greenhouse Gases (WDCGG), which is below 200 (WMO, 2009). GOSAT serves to fill in the blanks in the ground observation network.

2.3 Products retrieved from GOSAT TANSO-FTS SWIR spectra

The analysis of the TANSO-FTS SWIR spectra is described in detail by Yoshida et al. (2011). Briefly, absorption spectra at bands 1 and 2 are used together to retrieve CO\(_2\) and CH\(_4\) column abundances. From all spectra observed with TANSO-FTS SWIR, only those measured without cloud interference are selected for further processing. Based on the absorption characteristics of each gas, the selected spectra are used to retrieve column abundances of CO\(_2\) and CH\(_4\) (Level 2 product). The retrieval errors of \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) are on average 2 ppm and 8 ppb or about 0.5 % respectively. The retrieval errors include TANSO-FTS SWIR measurement noise, smoothing error and interference error, and the main error is the measurement noise (Yoshida et al., 2011). Variations in the CO\(_2\) concentration are most obvious near the surface of the earth. The CO\(_2\) absorption bands near 1.6 \(\mu\)m and 2.0 \(\mu\)m provide information on the near-surface concentrations. On the other hand, the TIR absorption band around 14 \(\mu\)m is used to obtain information on the profiles of CO\(_2\) and CH\(_4\), mainly at altitudes above 2 km (Saitoh et al., 2009). The retrievals from the TIR spectra and the validation of their products will be presented in a forthcoming paper.

Validation of the TANSO-FTS SWIR Level 2 data product is critical since the data are used for generating Level 3 and Level 4 products. GOSAT Level 2 products are evaluated against high-precision data obtained independently using ground-based or aircraft observations. Here we compare the GOSAT SWIR \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) results with those data obtained with ground-based high-resolution FTSs (g-b FTSs).

3 Reference data for GOSAT product validation

Spectra measured with g-b FTS are analyzed using the GFIT nonlinear least squares spectral fitting algorithm developed at the Jet Propulsion Laboratory (Toon et al., 1992; Wunch et al., 2011), which is used for retrievals across all stations that comprise the Total Carbon Column Observing Network (TCCON; Wunch et al., 2011). Here, we use the GFIT 7 Mar 2009 release.

The column-averaged volume mixing ratio of CO\(_2\) (\(X_{\text{CO}_2}\)) or CH\(_4\) (\(X_{\text{CH}_4}\)) is defined to be the ratio of the CO\(_2\) (or CH\(_4\)) column amount to the dry air column amount. To calculate the dry air column, the GFIT software uses the measured O\(_2\) column, divided by the known dry air mole fraction of O\(_2\) (0.2095). The O\(_2\) column is measured simultaneously with the CO\(_2\) and CH\(_4\) columns using the spectral band covering 1.25–1.29 \(\mu\)m. \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) are then obtained from:

\[
X_{\text{CO}_2} = 0.2095 \times (\text{CO}_2 \text{ column/O}_2 \text{ column})
\]

\[
X_{\text{CH}_4} = 0.2095 \times (\text{CH}_4 \text{ column/O}_2 \text{ column})
\]

Ratioing by O\(_2\) minimizes systematic and correlated errors present in both retrieved columns like pointing error, surface pressure uncertainty, instrument line shape uncertainty, H\(_2\)O vapor uncertainty, zero level offsets and solar intensity variation (e.g. thin clouds). We use “uncertainty” as

\[
\text{uncertainty}^2 = \text{accuracy}^2 + \text{precision}^2
\]

\[
\text{accuracy} = \text{bias} = \text{systematic error}
\]

\[
\text{precision} = \text{random error}
\]

The precision of g-b FTS measurement of \(X_{\text{CO}_2}\) is better than 0.2 % under clear sky conditions (Washenfelder et al., 2006; Ohyama et al., 2009; Wunch et al., 2011; Messerschmidt et al., 2010). All TCCON \(X_{\text{CO}_2}\) data are corrected for an airmass-dependent artifact (Wunch et al., 2011). Aircraft profiles obtained over many of these sites are used to determine an empirical scaling to place the TCCON data on the WMO standard reference scale. The scaling factors of \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) are 1.011 and 1.022, respectively. The uncertainty of \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) associated with the g-b FTS measurement is estimated to be 0.8 ppm (~0.2 %) and 4 ppb (~0.2 %) by comparing the TCCON retrievals with many different aircraft profiles (Wunch et al., 2010).

The g-b FTS data at nine TCCON sites are used in this analysis. Figure 1 shows the location of the FTS sites which are used in the present study. FTS sites are located in Asia, Oceania, Europe, and North America. Table 1 summarizes the spatial coordinates of those stations.

4 Results of initial validation

4.1 GOSAT product selection for validation

The GOSAT SWIR \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) products used here are Ver.01.xx. The retrieval algorithm for Ver.01.xx uses band 1 (12 900–13 200 cm\(^{-1}\)) and band 2 (5800–6400 cm\(^{-1}\)) to simultaneously estimate \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\). In addition, the water vapor column and aerosol optical depth (AOD) at a wavelength of 1.6 \(\mu\)m are retrieved. Band 3 is used for selecting scenes with cirrus clouds which CAI can not detect (Yoshida et al., 2011). Table 2 summarizes the spectral line parameters of CO\(_2\), CH\(_4\), H\(_2\)O and O\(_2\) molecules and the parameters
Table 1. Ground-based FTS sites used for GOSAT product validation.

Fig. 2. Global distribution of GOSAT SWIR $X_{CO_2}$ averaged monthly in 1.5 by 1.5 degree bins for (a) April and (b) October in 2009.

4.2 Global distribution of $X_{CO_2}$ and $X_{CH_4}$

Figures 2 and 3 show the global distribution of the monthly-averaged GOSAT SWIR $X_{CO_2}$ and $X_{CH_4}$ data, gridded in 1.5° by 1.5° bins in April and October 2009, respectively. These retrievals satisfy the filter criteria over North Africa, the Arabian Peninsula, and Australia. Data over land are obtained mainly for 10–60° N and 15–45° S in April, and 10–50° N and 0–50° S in October. Data over ocean are retrieved in the regions of 10° S–30° N in April and 40° S–10° N in October by observing the specular reflection of sunlight in the direction of sunglint.

$X_{CO_2}$ in April is generally higher in the Northern Hemisphere than the Southern Hemisphere (Fig. 2). This is because plant photosynthesis in the Northern Hemisphere is not yet competitive with respiration in April. In October, similar

$X_{CO_2}$ is observed in both hemispheres. The standard deviations of monthly mean $X_{CO_2}$ is about 1% for a 10° × 10° grid over Australia, where gradients are anticipated to be very small.

$X_{CH_4}$ in the Northern Hemisphere is higher than in the Southern Hemisphere in both April and October 2009 (Fig. 3). Elevated $X_{CH_4}$ is observed from India to Japan in October 2009. These features are similar to those obtained by SCIAMACHY (Frankenberg et al., 2006) and simulated by an inversion model (Bergamaschi et al., 2007).

GOSAT data are selected within about 0.5 to 1.5 degrees rectangular area centered at each FTS site depending on the geographical distribution of land and sea. As much as possible, we used only the GOSAT data retrieved over flat land.

4.3.1 X_CO₂

The time series of the GOSAT and g-b FTS data for X_CO₂ are shown on the left and their scatter diagrams on the right in Fig. 4. In the scatter diagram, we plotted data when g-b FTS data were collected within ±30 min of the GOSAT overpass time and corresponding GOSAT X_CO₂ values were successfully retrieved. Therefore, the number of the GOSAT data in the scatter diagram is less than that in the time series. Only a few GOSAT data are available for comparison with Bialystok, Garmisch, Park Falls and Lauder. Darwin FTS data were not obtained from May 2010 through September 2010 due to mechanical problems with the sun tracker. X_CO₂ retrieved from GOSAT SWIR measured near Orléans, Lamont and Tsukuba sites are higher in boreal spring and lower in autumn (Fig. 4b, e, and f). A clear seasonality over the Northern Hemisphere can also be seen in the maps in Fig. 2. In contrast, the seasonal variation of g-b FTS X_CO₂ in the Southern Hemisphere (i.e., Darwin, Wollongong, and Lauder) is weak (Fig. 4g, h, and i) as expected due to smaller contribution of the continents.

Figure 5 shows the scatter diagram between the GOSAT data and the g-b FTS data for all sites, and the slope of the regression line with no intercept is 0.977 with a correlation coefficient of 0.378 and Table 3 summarizes the difference of the GOSAT data to the g-b FTS data at each site. The difference of the GOSAT data to the g-b FTS data is −8.85 ± 4.75 ppm or −2.3 ± 1.2 %.

4.3.2 X_CH₄

The time series of the GOSAT and g-b FTS data for X_CH₄ are shown on the left and their scatter diagrams on the right in Fig. 6. The bias of X_CH₄ is smaller than that of X_CO₂.
Table 3. Left side: the average and one standard deviation (1\(\sigma\)) of the difference between GOSAT \(X_{\text{CO}_2}\) and g-b FTS \(X_{\text{CO}_2}\) for the nine TCCON sites. Right side: the average and one standard deviation (1\(\sigma\)) of the difference normalized to g-b FTS \(X_{\text{CO}_2}\) (given in percent). Note that the number of data listed here indicates the count of valid cases in which g-b FTS data were collected within \(\pm 30\) min of the GOSAT overpass time and corresponding GOSAT \(X_{\text{CO}_2}\) values were successfully retrieved.

In Lamont and Orléans, \(X_{\text{CH}_4}\) levels obtained from GOSAT SWIR are higher in boreal autumn. The g-b FTS data of \(X_{\text{CH}_4}\) over Tsukuba have a peak in summer rather than autumn.

Figure 7 shows the scatter diagram between the GOSAT data and the g-b FTS data for all sites. The slope of the regression line with no intercept is 0.998 and the correlation coefficient is 0.681. The difference between the GOSAT data and the g-b FTS data at each site is shown in Table 4. The difference of the GOSAT data to the g-b FTS data is \(-20.4 \pm 18.9\) ppb or \(-1.2 \pm 1.1\) %.

Fig. 4. Time series of GOSAT TANSO-FTS SWIR (blue triangles) and g-b FTS (pink squares) \(X_{\text{CO}_2}\) and their scatter diagrams for (a) Bialystok, (b) Orléans, (c) Garmisch, (d) Park Falls, (e) Lamont, (f) Tsukuba, (g) Darwin, (h) Wollongong, and (i) Lauder.

4.3.3 Remarks and relaxed coincidence criteria

There are too few data points in Tables 3 and 4 to compute meaningful statistics. For statistical significance, we have to consider all the data (62) in Tables 3 and 4. For Orléans, Lamont, Tsukuba and Wollongong, where there are more than 10 coincident data points in Table 3, site-dependent biases are the same within the mutual standard deviations. However, this is a topic for further investigation.

We relaxed the coincidence criteria. Comparison of the GOSAT data retrieved within \(\pm 2\) and \(\pm 5\) degrees latitude/longitude box centered at each g-b FTS site and the mean values of the g-b FTS data measured within \(\pm 1\) h of GOSAT overpass time can be found in Appendices A and B. For \(\pm 2\) degree latitude/longitude, the GOSAT \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) are biased low by \(8.57 \pm 4.44\) ppm (2.2 \(\pm 1\) %) and 15.8 \(\pm 22.3\) ppb (0.89 \(\pm 1.26\) %), respectively. For \(\pm 5\) degree latitude/longitude, the GOSAT \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) are biased low by \(8.25 \pm 3.97\) ppm (2.1 \(\pm 1\) %) and 14.8 \(\pm 22.6\) ppb (0.83 \(\pm 1.27\) %), respectively. These results are nearly equal to those in Tables 3 and 4. For these relaxed coincidence criteria, site-dependent biases of the GOSAT \(X_{\text{CO}_2}\) and \(X_{\text{CH}_4}\) are also the same within the mutual standard deviations.
Fig. 4. Continued.

Fig. 5. Scatter diagram between GOSAT TANSO-FTS SWIR and g-b FTS XCO₂ at all FTS sites.

Fig. 6. Time series of GOSAT TANSO-FTS SWIR (blue triangles) and g-b FTS (pink squares) XCH₄ and their scatter diagrams for (a) Bialystok, (b) Orléans, (c) Garmisch, (d) Park Falls, (e) Lamont, (f) Tsukuba, (g) Darwin, (h) Wollongong, and (i) Lauder.

because the standard deviations of the biases are large at respective FTS sites. However, the peak-to-peak variation of the biases from site to site is now 1.2–1.8 %. We have to investigate further to decrease the variation of the biases.

4.4 Latitudinal distributions of zonal averaged GOSAT SWIR XCO₂ and XCH₄

In Sect. 4.3, g-b FTS data recorded within ±30 min of the GOSAT overpass were used for the validation. To obtain larger numbers of samples and depict the latitudinal features, we calculated monthly mean XCO₂ and XCH₄ of g-b FTS data obtained within ±30 min of the time when GOSAT is supposed to overpass for all days, including the days when GOSAT does not overpass each site. In addition, monthly mean values of zonal averaged GOSAT data, based on all data obtained, are calculated in each 15 degree latitudinal band.

Latitudinal distributions of monthly means of zonal averaged GOSAT SWIR and g-b FTS data of XCO₂ in April and October 2009 are shown in Fig. 8. Both data sets show that XCO₂ is higher in the Northern Hemisphere compared with the Southern Hemisphere in April and the difference between...
the hemispheres is small in October. The difference of $X_{CO_2}$ between April and October is about 5 ppm in the northern mid latitudes for both data sets. The zonal means of GOSAT data are reasonably consistent with those of the reference values, apart from the overall biases.

Figure 9 shows latitudinal distributions of monthly means of zonal averaged GOSAT SWIR and g-b FTS data of $X_{CH_4}$ for April and October 2009. $X_{CH_4}$ is characterized by relatively high concentrations in the Northern Hemisphere in April and October. Moreover, the bias is smaller than that of $X_{CO_2}$. In particular, the concentration of $X_{CH_4}$ of GOSAT data is in good agreement with that of g-b FTS sites in April. Both $X_{CH_4}$ data in October show a similar distribution.

5 Discussion

In this study, we validated the GOSAT TANSO-FTS SWIR $X_{CO_2}$ and $X_{CH_4}$ against the TCCON g-b FTS instruments. In Ver.01.xx, the influence of aerosols has been markedly reduced compared with earlier versions of the retrievals (Yokota et al., 2009). The earlier versions (Ver.00.yy) used only band 2 of TANSO-FTS and retrieved $CO_2$ and $CH_4$ columns separately and estimates $X_{CO_2}$ and $X_{CH_4}$ using a dry-air column calculated from meteorological data analyzed by the Japan Meteorological Agency. Over the Sahara Desert and Arabian Peninsula and their surrounding areas, apparent high values of $X_{CO_2}$ and $X_{CH_4}$ were retrieved due to the influences of dust particles. In Ver.01.xx released in August 2010, bands 1 and 2 of TANSO-FTS were used for simultaneous retrieval of $CO_2$ and $CH_4$ columns with surface pressure. Therefore, the apparent high values of $X_{CO_2}$ and $X_{CH_4}$ almost disappeared over the Sahara Desert and their surrounding areas thanks to the correction of the extended optical paths by the elevated dust particles.

However, bias due to aerosols and thin cirrus clouds still exists because of the anomalously low $X_{CO_2}$ retrievals (Fig. 2). In the future, we plan to investigate interferences by aerosols and thin cirrus clouds using aerosol lidars and/or sky-radiometers at selected FTS sites.

The negative bias of about 9 ppm or 2.3 % in the GOSAT TANSO-FTS SWIR data of $X_{CO_2}$ is not still understood. It may result from unknown spectroscopic parameters of $O_2$ and $CO_2$ or error in the TANSO-FTS calibration. In the case of the GOSAT SWIR data of $X_{CH_4}$, the negative bias decreased in the Ver.01.xx compared with the earlier Ver.00.yy when the spectroscopic parameters were changed from Lyulin et al. (2009) to HITRAN 2008 database (Rothman et al., 2009). Therefore it is important to further examine the spectroscopic parameters of $O_2$, $CO_2$ and $CH_4$.

Some instrumental issues occurred since the launch of GOSAT, which could also contribute to the biases. The sampling laser wavelength of TANSO-FTS shifted in time probably due to the change of the 1.31-µm distributed-feedback laser cavity length. The sensitivity of band 1 decreased after
the launch. These effects are corrected before retrieving $X_{CO_2}$ and $X_{CH_4}$. A TANSO-FTS pointing error occurred when the pointing mirror was moved largely to the along-track direction. This error causes the mismatch of the field of views between CAI and TANSO-FTS, and misleads the cloud screening algorithm. However, in the case of the special point observation mode of TANSO-FTS to g-b FTS sites, the mismatch should be small.

The standard deviation of the GOSAT SWIR $X_{CO_2}$ and $X_{CH_4}$ is about 1 % ($1\sigma$) after correcting the negative biases by 8.85 ppm and 20.4 ppb, respectively, and it is larger than that of the g-b FTS data ($\sim$0.2 %). The retrieval errors of $X_{CO_2}$ and $X_{CH_4}$ are on average 2 ppm and 8 ppb or about 0.5 % respectively. This means that the other errors of about 0.5 % are due to influences of factors such as aerosols and thin cirrus clouds. In the retrieval algorithm of Ver.01.xx, aerosols are assumed to exist homogeneously below 2-km altitude. In the near future retrieval algorithm, the vertical profiles of aerosols will be simultaneously retrieved with $X_{CO_2}$ and $X_{CH_4}$. This could decrease the standard deviation of the GOSAT $X_{CO_2}$ and $X_{CH_4}$. To what extent topographies surrounding g-b FTS sites influence the data quality, is not clear at present. We will investigate this effect in the near future.

6 Conclusions

The GOSAT TANSO-FTS SWIR data of $X_{CO_2}$ and $X_{CH_4}$ in the Version 01.xx were compared against reference data obtained with the TCCON g-b FTS sites. The GOSAT TANSO-FTS SWIR $X_{CO_2}$ and $X_{CH_4}$ were biased low by 8.85 ± 4.75 ppm (2.3 ± 1.2 %) and 20.4 ± 18.9 ppb (1.2 ± 1.1 %) respectively versus the reference values. The standard deviation of the GOSAT SWIR $X_{CO_2}$ and $X_{CH_4}$ retrievals is considered to be about 1 % ($1\sigma$) after correcting the negative biases by 8.85 ppm and 20.4 ppb, respectively.

Although $X_{CO_2}$ is underestimated by approximately 9 ppm, the GOSAT retrievals and g-b FTS data show similar seasonal behaviors over the Northern Hemisphere: higher in spring and lower in autumn. The latitudinal distribution of zonal averaged GOSAT SWIR $X_{CO_2}$ and $X_{CH_4}$ is broadly consistent with that of the g-b FTS except for the larger negative biases in the GOSAT data. We plan further studies to address the negative bias of the GOSAT SWIR $X_{CO_2}$ and $X_{CH_4}$ as well as to better understand the influence of aerosols and thin cirrus clouds.
Table A1. Left side: the average and one standard deviation (1σ) of the difference between GOSAT $X_{\text{CO}_2}$ and g-b FTS $X_{\text{CO}_2}$ for the nine TCCON sites. Right side: the average and one standard deviation (1σ) of the difference normalized to g-b FTS $X_{\text{CO}_2}$ (given in percent). The GOSAT data were retrieved within ±2 degrees latitude/longitude box centered at each g-b FTS site and the g-b FTS data were the mean values measured within ±1 h of GOSAT overpass time.

Appendix A

Comparison of GOSAT and g-b FTS data within ±2 degrees and ±1 h

We performed comparison of the GOSAT data retrieved within ±2 degrees latitude/longitude box centered at each g-b FTS site and the mean values of the g-b FTS data measured within ±1 h of GOSAT overpass time.

The time series of the GOSAT and g-b FTS data for $X_{\text{CO}_2}$ are shown on the left and their scatter diagrams on the right in Fig. A1. Figure A2 shows the scatter diagram between the GOSAT data and the g-b FTS data for all sites, and the slope of the regression line with no intercept is 0.978 with a correlation coefficient of 0.319 and Table A1 summarizes the difference of the GOSAT data to the g-b FTS data at each site. The difference of the GOSAT data to the g-b FTS data is $-8.57 \pm 4.44$ ppm or $-2.2 \pm 1.2 \%$.

The time series of the GOSAT and g-b FTS data for $X_{\text{CH}_4}$ are shown on the left and their scatter diagrams on the right in Fig. A3. Figure A4 shows the scatter diagram between the GOSAT data and the g-b FTS data for all sites. The slope of the regression line with no intercept is 0.991 and the correlation coefficient is 0.794. The difference between the GOSAT data and the g-b FTS data at each site is shown in Table A2. The difference of the GOSAT data to the g-b FTS data is $-15.8 \pm 22.3$ ppb or $-0.89 \pm 1.3 \%$.

Fig. A1. Time series of GOSAT TANSO-FTS SWIR (blue triangles) and g-b FTS (pink squares) $X_{\text{CO}_2}$, and their scatter diagrams for (a) Bialystok, (b) Orleans, (c) Garmisch, (d) Park Falls, (e) Lamont, (f) Tsukuba, (g) Darwin, (h) Wollongong, and (i) Lauder. The GOSAT data were retrieved within ±2 degrees latitude/longitude box centered at each g-b FTS site and the g-b FTS data were the mean values measured within ±1 h of GOSAT overpass time.
Fig. A1. Continued.

Fig. A2. Scatter diagram between GOSAT and g-b FTS $X_{CO_2}$ at all FTS sites. The GOSAT data were retrieved within ±2 degrees latitude/longitude box centered at each g-b FTS site and the g-b FTS data were the mean values measured within ±1 h of GOSAT overpass time.

Fig. A3. Time series of GOSAT TANSO-FTS SWIR (blue triangles) and g-b FTS (pink squares) $X_{CH_4}$ and their scatter diagrams for (a) Bialystok, (b) Orléans, (c) Garmisch, (d) Park Falls, (e) Lamont, (f) Tsukuba, (g) Darwin, (h) Wollongong, and (i) Lauder. The GOSAT data were retrieved within ±2 degrees latitude/longitude box centered at each g-b FTS site and the g-b FTS data were the mean values measured within ±1 h of GOSAT overpass time.

Appendix B

Comparison of GOSAT and g-b FTS data within ±5 degrees and ±1 h

We performed comparison of the GOSAT data retrieved within ±5 degrees latitude/longitude box centered at each g-b FTS site and the mean values of the g-b FTS data measured within ±1 h of GOSAT overpass time.

The time series of the GOSAT and g-b FTS data for $X_{CO_2}$ are shown on the left and their scatter diagrams on the right in Fig. B1.

Figure B2 shows the scatter diagram between the GOSAT data and the g-b FTS data for all sites, and the slope of the regression line with no intercept is 0.979 with a correlation coefficient of 0.285 and Table B1 summarizes the difference of the GOSAT data to the g-b FTS data at each site.
Table B1. Left side: the average and one standard deviation (1σ) of the difference between GOSAT \(X_{\text{CO}_2}\) and g-b FTS \(X_{\text{CO}_2}\) for the nine TCCON sites. Right side: the average and one standard deviation (1σ) of the difference normalized to g-b FTS \(X_{\text{CO}_2}\) (given in percent). The GOSAT data were retrieved within ±5 degrees latitude/longitude box centered at each g-b FTS site and the g-b FTS data were the mean values measured within ±1 h of GOSAT overpass time.
