Search for new physics in final states with a lepton and missing transverse energy in $pp$ collisions at the LHC

S. Chatrchyan et al.*
(CMS Collaboration)
(Received 12 February 2013; published 8 April 2013)

This Letter describes the search for an enhanced production rate of events with a charged lepton and a neutrino in high-energy $pp$ collisions at the LHC. The analysis uses data collected with the CMS detector, with an integrated luminosity of 5.0 $fb^{-1}$ at $\sqrt{s} = 7$ TeV, and a further 3.7 $fb^{-1}$ at $\sqrt{s} = 8$ TeV. No evidence is found for an excess. The results are interpreted in terms of limits on a heavy charged gauge boson ($W'$) in the sequential standard model, a split universal extra dimension model, and contact interactions in the helicity-nonconserving model. For the last, values of the binding energy below 10.5 (8.8) TeV in the electron (muon) channel are excluded at a 95% confidence level. Interpreting the $\ell\nu$ final state in terms of a heavy $W'$ with standard model couplings, masses below 2.90 TeV are excluded.

DOI: 10.1103/PhysRevD.87.072005 PACS numbers: 12.60.Cn, 13.85.Rm, 14.70.Pw

I. INTRODUCTION

New heavy gauge bosons are predicted by various extensions of the standard model (SM). The sequential standard model (SSM) [1] postulates the existence of a $W'$ boson, a heavy analogue of the $W$. In such a theory, the $W'$ is expected to appear as a narrow resonance with decay modes and branching fractions similar to those of the $W$. For $W'$ masses above 180 GeV, where the $t\bar{b}$ decay channel opens up, the predicted branching fraction is about 8.5% for each of the leptonic final states. Previous searches [2,3] with $pp$ collision data at $\sqrt{s} = 7$ TeV by the Compact Muon Solenoid (CMS) and ATLAS experiments at the Large Hadron Collider (LHC), based on an integrated luminosity of up to 5 $fb^{-1}$, have excluded SSM $W'$ bosons with masses up to 2.6 TeV.

Other models for new physics predict the same final state, such as those with universal extra dimensions (UED) and bulk fermions, or split UED [4,5]. Such models of extended space-time assume one additional compact dimension of radius $R$. The split-UED parameter space is defined by $1/R$ and $\mu$, with $\mu$ being the bulk mass parameter of the fermion field in five dimensions. For suitable nonzero values of $\mu$, as assumed by split-UED models, the cross sections are sufficiently large to allow observation by LHC experiments. All SM particles have corresponding Kaluza-Klein (KK) partners, for instance $W^n_{KK}$, where $n$ denotes the $n$th KK excitation mode. Only KK-even modes of $W^n_{KK}$ couple to SM fermions, owing to KK-parity conservation [6]. Modes with $n \geq 4$ have a smaller cross section and are not expected to be accessible at $\sqrt{s} = 8$ TeV, hence the only mode considered is $n = 2$.

Motivated by the observation of mass hierarchies in the fermion sector, theories have been developed where leptons and quarks are composite objects [7]. At energies much lower than the binding energy of these fundamental constituents, typically called $\Lambda$, quark and lepton compositeness would manifest itself as a four-fermion contact interaction (CI). One of the possible contact interactions between two quarks, a neutrino, and a charged lepton, is described by the helicity-nonconserving (HNC) model [8]. The corresponding cross section is proportional to the square of the partonic center-of-mass energy and to $\Lambda^{-4}$. While CDF has set a limit on $\Lambda > 2.81$ TeV [9] based on a final state with an electron and a neutrino, no limit in the HNC model has yet been set in the muon channel.

In this Letter, a search is presented for an excess of events with an isolated charged lepton (an electron or muon) and a neutrino in the final state, using the CMS detector. The data sample corresponds to an integrated luminosity of 5.0 $fb^{-1}$ at $\sqrt{s} = 7$ TeV collected in 2011, and 3.7 $fb^{-1}$ at $\sqrt{s} = 8$ TeV collected in 2012. The CMS 2011 result has been published in Ref. [2].

II. THE CMS DETECTOR

The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the superconducting solenoid volume are a silicon pixel and strip tracker, a lead tungstate crystal electromagnetic calorimeter, and a brass and scintillator hadron calorimeter. Muons are measured in gas-ionization detectors embedded in the steel return yoke. Extensive forward calorimetry complements the coverage provided by the barrel and end cap detectors. A more detailed description of the CMS detector can be found in Ref. [10]. CMS uses a right-handed coordinate system, with the origin at the nominal interaction point, the $x$

axis pointing to the center of the LHC, the y axis pointing up (perpendicular to the LHC plane), and the z axis along the anticlockwise-beam direction. The polar angle $\theta$ is measured from the positive z axis and the azimuthal angle $\phi$ is measured in the x-y plane.

### III. THE SEARCH STRATEGY

Candidate events with at least one high transverse momentum ($p_T$) electron or muon are selected using single-lepton triggers. Isolated high-$p_T$ leptons are reconstructed using very stringent quality criteria while the neutrino gives rise to experimentally observed missing transverse energy ($E_T^{\text{miss}}$). The details on lepton identification and $E_T^{\text{miss}}$ reconstruction, as optimized for the 2011 analysis, can be found in Ref. [2]. The discriminating variable of this analysis is the transverse mass $M_T$ of the lepton-$E_T^{\text{miss}}$ system, calculated as

$$M_T = \sqrt{2 \cdot p_T^l \cdot E_T^{\text{miss}} \cdot (1 - \cos \Delta \phi_{l,\nu})},$$

where $\Delta \phi_{l,\nu}$ is the azimuthal angle between the charged lepton’s transverse momentum $p_T^l$ and the $E_T^{\text{miss}}$ direction.

In $W'$ decays, as well as for the other models considered, the lepton and $E_T^{\text{miss}}$ are expected to be almost back to back in the transverse plane, and balanced in transverse energy. Additional kinematic criteria therefore select events with a ratio of the lepton $p_T^l$ and the $E_T^{\text{miss}}$ of $0.4 < p_T^l / E_T^{\text{miss}} < 1.5$, along with the requirement of the angular difference, $|\Delta \phi_{l,\nu} - \pi| < 0.2 \pi$. For simulated SSM $W'$ events with masses between 0.5 and 2.5 TeV passing these selection criteria, the signal efficiency (including 90% geometrical acceptance) is found to be 70%–75% with 2% uncertainty in the electron channel and 67%–72% with 1% uncertainty in the muon channel. For the HNC contact-interaction model the signal efficiency is independent of the interaction scale $\Lambda$ and has been determined from simulation to be 80% with 1% uncertainty for the electron channel and 77% with 4% uncertainty for the muon channel. The transverse mass distributions for accepted SM events in the electron and muon channels are shown in Fig. 1, along with two example $W'$ signals. The observed event with the highest transverse mass in the electron channel has $M_T = 2.38 \pm 0.05$ TeV based on $E_T = 1.2$ TeV with 1% uncertainty. In the muon channel the maximum transverse mass is $M_T = 1.33 \pm 0.03$ TeV with a measured $p_T^l$ of 690 $\pm$ 22 GeV. The two types of processes, $W'$ production and compositeness, can be distinguished by examining the shape of the lepton-$E_T^{\text{miss}}$ transverse mass spectrum. Both processes manifest themselves through an excess of events at the

![FIG. 1 (color online). Observed lepton-$E_T^{\text{miss}}$ transverse mass distributions in the electron (top) and the muon (bottom) channel. The dashed lines show the parametrization of the background as described in the text (labeled as BG parametrization in the legend). Simulated signal distributions for a SSM $W'$ are also shown, including detector resolution effects. The simulated background labeled as “diboson” includes $WW$, $ZZ$, and $WZ$ contributions. The last bin contains the contributions of all bins above the displayed range.](image1)

high end of the spectrum. The $W'$ signal events are expected to concentrate in a Jacobian peak around the $W'$ mass, as shown in Fig. 1. Compositeness would rather yield an unstructured excess, with the excess relative to the standard model contribution increasing as a function of $M_T$, as shown in Fig. 2.

IV. SIGNAL AND BACKGROUNDS

The $W'$ (this also includes $W_{KK}^{n=2}$) and CI signals are generated at leading order (LO) with PYTHIA 6.4.26 [11] using the CTEQ6L1 [12] parton distribution functions. They are scaled to the next-to-next-to-leading order (NNLO) cross section calculated with FEWZ [13,14] for each $W'$ ($W_{KK}^{n=2}$) mass point. In the absence of higher-order calculations, LO cross sections are used for the CI model.

The primary source of background is the off-peak, high-$M_T$ tail of the standard model $W 	o \ell \nu$ decays. Other important backgrounds arise from $t\bar{t}$, Drell-Yan, and diboson ($WW$, $WZ$, $ZZ$) events. An important background also comes from QCD multijet processes, but this is largely removed by the analysis selections and therefore cannot be readily distinguished in Fig. 1. Contributions from decays with $\tau$ leptons in the final state that subsequently decay to an electron or muon and neutrinos are considered as well, but found to be negligible. The PYTHIA 6 generator is used for all background processes except for $t\bar{t}$, which is generated with MADGRAPH 4 [15] in combination with PYTHIA. The numbers of Monte Carlo events are normalized using the integrated luminosity of the recorded data and with NNLO cross sections, except diboson and multijet samples, for which the next-to-leading order and LO cross sections are used, respectively. In all event samples, additional minimum bias interactions are superimposed onto the main background processes to match the luminosity profile of the analyzed data set.

FIG. 3 (color online). Limits on the cross section times the single channel branching fraction ($\sigma \times B$) for heavy bosons based on the 2012 data for the electron and the muon channels. For the individual channels, only the observed limits are shown. For the combination, the observed limit, the expected limit, the $1\sigma$, and the $2\sigma$ bands are displayed. The model assumes equal branching fractions for the electron and the muon channel, hence the combination corresponds to doubling the number of events. All limits are displayed for the single channel branching fraction. The $W'$ mass limits are derived with a Bayesian method for the models of a SSM $W'$ and $W_{KK}^{n=2}$ in split UED. The $W_{KK}^{n=2}$ is the lowest mass state that can couple to SM fermions and has the same final state as the SM-like $W'$. Because it has even KK parity, it can be produced singly.

The background prediction is based on the transverse mass distributions of these simulations, as seen in Fig. 1. The summed background distribution is parametrized with a function of form $f(M_T) = \frac{a}{(M_T+b)^p}$ to avoid event...
prior distribution in the same way as in our previous analysis from Ref. [2]. The lepton-energy calibration and resolution distort the transverse mass spectrum. Uncertainties in the energy scale and the energy resolution make comparable contributions to the overall uncertainty in the electron channel; the energy scale has an uncertainty of 1(3)% in the barrel (end caps) and the resolution has an uncertainty of 1.4(3)% for the barrel (end caps) [16]. For muons, the dominant uncertainty stems from the momentum scale, which is taken to be 5% × p_{T}/TeV [17] and results in larger errors on the background and signal event yields in the muon channel, as can be seen in Table I. The muon p_{T} resolution has been determined with cosmic ray muons to be 10% at high p_{T} with an uncertainty of 0.6% [17].

Similarly, the impact of the E_{T}^{miss} energy scale is modeled by shifting the hadronic component event by event by 10%, while the resolution is taken into account by a 10% smearing. In all cases, the impact on the expected number of signal events is around 1% for each source of uncertainty. The background parametrization procedure is repeated using the distorted distributions. Additionally, an uncertainty is derived by fitting the undistorted background with two different functions. The estimates shown in Table I include a systematic uncertainty that covers the range of results from these fits, with the statistical uncertainty coming from the fit to the original distribution. Additionally, an uncertainty of 4.4% is considered on the integrated luminosity [18].

The number of data events above a transverse mass threshold M_{T}^{min} is compared to the expected number of signal and background events, with the M_{T}^{min} threshold being optimized for the best expected exclusion limit, using steps of 50 GeV. Very similar results are achieved

\begin{table}[h]

\end{table}

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figures/comparison.png}
\caption{Combination of 2011 and 2012 data for the electron and the muon channels using 5.0 fb^{-1} of data at \sqrt{s} = 7 TeV from 2011 and 3.7 fb^{-1} of data at \sqrt{s} = 8 TeV from 2012. The left and middle plots show the individual combinations for the electron (left) and muon channel (right). To the right the combination of both is displayed. The limits are derived with a Bayesian method. Plotted is the signal strength modifier $\sigma_{\text{excl}}/\sigma_{\text{SSM W'}}$ as a function of the W' mass, where $\sigma_{\text{excl}}$ is the cross section excluded at a 95% C.L. and $\sigma_{\text{SSM W'}}$ is the cross section predicted by the SSM. All W' mass points below the ratio $\sigma_{\text{excl}}/\sigma_{\text{SSM W'}} = 1$, shown as a red dashed line, are excluded in the sequential standard model.}
\end{figure}
when optimizing for discovery. The same optimization procedure is applied for the $W'$ and CI searches but the optimized $M_T$ thresholds are specific to each analysis. For a $W'$ mass of up to 2.5 TeV the optimization tends to select a value for $M_T^{\text{min}}$ a little below the peak of the Jacobian, retaining most of the events in the peak. To keep a significant signal contribution for higher masses, the $M_T^{\text{min}}$ threshold is shifted to lower values owing to the increasing off-shell fraction. For CI no such effect exists and the optimized $M_T^{\text{min}}$ threshold is roughly constant around 1 TeV.

No significant excess has been observed in the data, and upper limits are set on the production cross section times the branching fraction $\sigma \times \mathcal{B}(W' \rightarrow \ell \nu)$, with $\ell = e$ or $\mu$, using a Bayesian method with the assumption of a flat prior for the parameter of interest. The expected and observed upper cross section limits on a SSM $W'$, at 95% confidence level (C.L.), for $\sqrt{s} = 8$ TeV data, are shown in Fig. 3 for both channels and their combination. Using the central value of the theoretical NNLO SSM $W'$ cross section times branching fraction, which is assumed to be identical in the two channels, we exclude masses less than 2.60 TeV in the electron and 2.75 TeV in the muon channel. The expected limits are 2.70 TeV and 2.65 TeV, respectively. The observed limit for $W' \rightarrow e \nu$ is slightly lower than the expectation because of one event with a transverse mass of 2.3 TeV (Fig. 1). Combining both channels, the limit increases to 2.85 TeV (Table II). To further enhance the sensitivity, the new results can be combined with the published [2] $\sqrt{s} = 7$ TeV results, based on an integrated luminosity of 5 fb$^{-1}$, thus extending the limit to 2.90 TeV as shown in Fig. 4 and Table II.

The limit can be reinterpreted in terms of the $W'_{KK}$ mass, as shown in Fig. 3, for values of the Dirac mass term $\mu = 0.05$ TeV and $\mu = 10$ TeV and directly translated to bounds on the split-UED parameter space, $(1/R, \mu)$ (Fig. 5). The four-fermion contact interaction of the HNC model is excluded for values of $\Lambda < 10.5$ TeV in the electron channel and $\Lambda < 8.8$ TeV in the muon channel (Fig. 6). While the expected sensitivity is comparable in both search channels, the exclusion limit in the electron

FIG. 5 (color online). The 95% C.L. limits on the split-UED parameters $\mu$ and $1/R$ derived from the $W'$ mass limits taking into account the corresponding width of the $W'_{KK}$. For the 3.7 fb$^{-1}$ of 2012 data, the individual limits for the electron and muon channels are shown together with their combination, improving the excluded parameter space based on the 2011 data shown in yellow.

FIG. 6 (color online). Bayesian limits on the cross section times the single channel branching fraction ($\sigma \times \mathcal{B}$) for contact interactions (HNC model) in the electron + $E_T^{\text{miss}}$ (top) and the muon + $E_T^{\text{miss}}$ channel (bottom) based on an integrated luminosity of 3.7 fb$^{-1}$ of $\sqrt{s} = 8$ TeV data. The expected limit in either channel excludes values of the new interaction scale $\Lambda < 9$ TeV. The observed limit, driven by the data, excludes $\Lambda < 10.5$ TeV (8.8) in the electron (muon) channel. The signal efficiency is independent of $\Lambda$. 
The channel is higher because of a downward fluctuation of data (see Table I) in the search region of $M_T > 1$ TeV. These limits are summarized in Table III.

### VI. SUMMARY

A search for new physics has been carried out using $pp$ collisions recorded with the CMS detector at center-of-mass energies of $\sqrt{s} = 7$ and 8 TeV. The transverse mass spectrum of either electrons or muons and missing transverse energy has been measured. The observed spectra are consistent with the standard model expectation, and mass limits on sequential standard model $W'$ and $W_{KK}'$ have been set at the 95% C.L. These are the most stringent limits to date. For the first time, a limit on the compositeness scale $\Lambda$ has been set for contact interactions in the HNC model based on the final state with a muon and $E_T^{miss}$. The corresponding exclusion limit in the electron channel significantly improves the existing one.

### ACKNOWLEDGMENTS

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MEYS (Bulgaria); CERN; CAS, MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09, and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NKTH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); NRF and WCU (Republic of Korea); LAS (Lithuania); CINVESTAV, CONACYT, SEP, and UASLP-FAI (Mexico); MSI (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Armenia, Belarus, Georgia, Ukraine, Uzbekistan); MON, RosAtom, RAS, and RFBR (Russia); MSTD (Serbia); SEIDI and CPAN (Spain); Swiss Funding Agencies (Switzerland); NSC (Taipei); ThEPCenter, IPST and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

sAlso at Institute of Nuclear Research ATOMKI, Debrecen, Hungary.
tAlso at Eötvös Loránd University, Budapest, Hungary.
uAlso at Tata Institute of Fundamental Research – HECR, Mumbai, India.
wNow at King Abdullahiaz University, Jeddah, Saudi Arabia.
xAlso at University of Visva-Bharati, Santiniketan, India.
yAlso at Sharif University of Technology, Tehran, Iran.
zAlso at Isfahan University of Technology, Isfahan, Iran.
Also at Shiraz University, Shiraz, Iran.
aaAlso at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran.
bbAlso at Facoltà Ingegneria, Università di Roma, Roma, Italy.
cA Also at Università degli Studi Guglielmo Marconi, Roma, Italy.
dA Also at Università degli Studi di Siena, Siena, Italy.
eA Also at University of Bucharest, Faculty of Physics, Bucuresti-Magurele, Romania.
fA Also at Faculty of Physics, University of Belgrade, Belgrade, Serbia.
gA Also at University of California, Los Angeles, CA, USA.
hA Also at Scuola Normale e Sezione dell’INFN, Pisa, Italy.
ii Also at INFN Sezione di Roma, Roma, Italy.
jjAlso at University of Athens, Athens, Greece.
kA Also at Rutherford Appleton Laboratory, Didcot, United Kingdom.
lA Also at Paul Scherrer Institut, Villigen, Switzerland.
mmAlso at Institute for Theoretical and Experimental Physics, Moscow, Russia.
nnAlso at Albert Einstein Center for Fundamental Physics, Bern, Switzerland.
ooAlso at Gaziosmanpasa University, Tokat, Turkey.

PHYSICAL REVIEW D 87, 072005 (2013)

pp Also at Adiyaman University, Adiyaman, Turkey.
qq Also at Izmir Institute of Technology, Izmir, Turkey.
rr Also at The University of Iowa, Iowa City, IA, USA.
ss Also at Mersin University, Mersin, Turkey.
tt Also at Ozyegin University, Istanbul, Turkey.
uu Also at Kafkas University, Kars, Turkey.
vv Also at Suleyman Demirel University, Isparta, Turkey.
wv Also at Ege University, Izmir, Turkey.
xw Also at Mimar Sinan University, Istanbul, Istanbul, Turkey.
xz Also at Kahramanmaras Sütçü Imam University, Kahramanmaras, Turkey.
xz Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom.
xyz Also at INFN Sezione di Perugia, Università di Perugia, Perugia, Italy.
bbb Also at Utah Valley University, Orem, UT, USA.
ccc Now at University of Edinburgh, Scotland, Edinburgh, United Kingdom.
ddd Also at Institute for Nuclear Research, Moscow, Russia.
eee Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia.
fff Also at Argonne National Laboratory, Argonne, IL, USA.
ggg Also at Erzincan University, Erzincan, Turkey.
hhh Also at KFKI Research Institute for Particle and Nuclear Physics, Budapest, Hungary.
iii Also at Kyungpook National University, Daegu, Korea.
