THE BIRMAN–MURAKAMI–WENZL ALGEBRAS OF TYPE $D_n$

ARJEH M. COHEN & DIÉ A.H. GIJSBERS & DAVID B. WALES

Abstract. The Birman–Murakami–Wenzl algebra (BMW algebra) of type $D_n$ is shown to be semisimple and free of rank $(2^n + 1)n! - (2^{n-1} + 1)n!$ over a specified commutative ring $R$, where $n!! = 1 \cdot 3 \cdots (2n - 1)$. We also show it is a cellular algebra over suitable ring extensions of $R$. The Brauer algebra of type $D_n$ is the image of an $R$-equivariant homomorphism and is also semisimple and free of the same rank, but over the ring $\mathbb{Z}[\delta^{\pm 1}]$. A rewrite system for the Brauer algebra is used in bounding the rank of the BMW algebra above. As a consequence of our results, the generalized Temperley–Lieb algebra of type $D_n$ is a subalgebra of the BMW algebra of the same type.

1. Introduction

In [2], Birman and Wenzl, and independently in [21], Murakami, defined algebras indexed by the natural numbers which play a role in both the representation theory of quantum groups and knot theory. They were given by generators and relations. In [23], Morton and Wasserman gave them a description in terms of tangles. These are the Birman–Murakami–Wenzl algebras (usually abbreviated to BMW algebras) for the Coxeter system of type $A_n$. They behave nicely with respect to restriction to the algebras generated by subsets of the generators. For instance, the BMW algebras of a restricted type embed naturally into the bigger ones. This is similar to the fact that in Weyl groups subgroups generated by subsets of the standard reflections are themselves Weyl groups. The Hecke algebra of type $A_n$ is a natural quotient of the Birman–Murakami–Wenzl algebra of type $A_n$ and the Temperley–Lieb algebra, conceived originally for statistics (cf. [26]), is a natural subalgebra. Inspired by the beauty of these results, the existence of Temperley–Lieb algebras of other types ([11, 15, 17, 18]) and the existence of a faithful linear representation of the braid group ([10, 12]), the authors defined analogues for other simply laced Coxeter diagrams and found some of their properties in [5]. The faithful linear representations of the braid group were shown first by Bigelow in [1] and Krammer in [20]. They used a representation introduced by Lawrence in [21].

In this paper we consider the algebras when the Coxeter diagram is of type $D_n$. We prove the conjecture stated in [5, Section 7.1], which is Theorem [11,1.1]. Here, $n!! = 1 \cdot 3 \cdots (2n - 1)$. We work over the quotient ring $R$ of $\mathbb{Z}[\delta, \delta^{-1}, l, l^{-1}, m]$ by
the ideal generated by \( m(1 - \delta) - (l - l^{-1}) \) instead of the field \( \mathbb{Q}(l, \delta) \) in which it embeds (see Lemma 3.7).

**Theorem 1.1.** The BMW algebra of type \( D_n \) over \( R \) is free of rank
\[
(2^n + 1) n! - (2^{n-1} + 1) n!.
\]
When tensored with \( \mathbb{Q}(l, \delta) \), it is semisimple.

The result produces linear representations of the Artin group of type \( D_n \), similar to the representations of the braid group on \( n \) strands which arose from the BMW algebra of type \( A_{n-1} \). These include the faithful representations related to the Lawrence–Krammer representations occurring in [9] as well as the representations occurring in [5]. Furthermore, specific information about the representations is given in terms of sets of orthogonal roots and irreducible representations of Weyl groups of type \( D_r \) for certain \( r \) (cf. Remark 7.5).

These sets of orthogonal roots are also used in the description of a cellular basis, whose elements are determined by pairs of such root sets and a Weyl group element. This leads, for suitable extensions of the coefficient ring \( R \), to cellularity of the BMW algebra \( B(D_n) \) in the sense of [16, Definition 1.1]. For \( B(A_n) \), this result is known thanks to [28].

**Theorem 1.2.** The BMW algebra of type \( D_n \) is cellular if the coefficient ring \( R \) is extended to an integral domain containing an inverse to 2.

As a consequence of the work we are able to show the Temperley–Lieb algebra of type \( D_n \) as defined in [11, 15, 18] is a natural subalgebra.

**Corollary 1.3.** The generalized Temperley–Lieb algebra of type \( D_n \) is a natural subalgebra of both the Brauer algebra and the BMW algebra of type \( D_n \) over the rings \( \mathbb{Z}[\delta, \delta^{-1}] \) and \( R \), respectively.

The current work completes the proof that there is an isomorphism from the BMW algebra to the algebra of tangles having a pole of order 2 studied in [7]. For each element of the cellular basis, the two corresponding root sets determine the set of horizontal strands at the top and bottom, respectively, and the corresponding Weyl group element determines the vertical strands of the tangle. The isomorphism is discussed at the end of this paper.

Putting together [23], Theorem 1.1 and the main theorem of [8], we have reached a complete description of the BMW algebras of spherical simply laced type.

2. **Overview**

We proceed as follows. First, in Section 3 we introduce the BMW algebra \( B(M) \) over \( R \) for \( M \) of type \( A_n \) (\( n \geq 1 \)), \( D_n \) (\( n \geq 4 \)), or \( E_n \) (\( n = 6, 7, 8 \)), which we denote ADE. Then the Brauer algebra, \( Br(M) \), of the same type over \( \mathbb{Z}[\delta \pm 1] \) is obtained from \( B(M) \) by specializing \( m \) to 0 and \( l \) to 1. This algebra was defined in [4] where it was shown to be free over \( R \) of rank \( (2^n + 1) n! - (2^{n-1} + 1) n! \) in case \( M = D_n \). The modding out of \( m \) and \( l - 1 \) gives a surjective \( R \)-equivariant map \( \mu : B(M) \to Br(M) \).

The Brauer algebra \( Br(M) \) is given in terms of generators \( e_i, r_i \) for \( i \) running over the nodes of \( M \), and relations determined by \( M \) (cf. Definition 3.3). The subalgebra of \( Br(M) \) generated by the \( r_i \) is the group algebra over \( \mathbb{Z}[\delta \pm 1] \) of \( W(M) \), the Coxeter group of type \( M \).
The specialization enables us to pass from monomials in $\mathbb{B}(D_n)$ to monomials in $\mathbb{B}(D_n')$. We will use this observation to find a basis of monomials for $\mathbb{B}(D_n)$ from a similar basis in $\mathbb{B}(D_n')$.

In Section 4 we summarize results from [4] and [6] which show how the monomials of $\mathbb{B}(M)$ determine sets of mutually orthogonal roots, which in the case $M = A_{n-1}$ are directly related to tops and bottoms of the well-known Brauer diagrams. The monomials, including powers of $\delta$, form a monoid inside $\mathbb{B}(M)$, denoted $\mathbb{B}M(M)$ (see Definition 3.3).

In Sections 5 and 6 we use the following strategy to produce a basis of $\mathbb{B}(D_n)$ from elements of $\mathbb{B}M(D_n)$. A word $a$ in the generators of the Brauer monoid $\mathbb{B}M(M)$ is said to be of height $t$ if the number of generators $r_i$ occurring in it is equal to $t$. We say that $a$ is reducible to another word $b$ if $b$ can be obtained from $a$ by a finite sequence of specified rewrite rules (listed in Table 2) that do not increase the height. This process will be called a reduction. The significance of such a reduction is that the word $a$ also corresponds to a unique monomial in the BMW algebra and that a parallel reduction (with rules listed in Table 1) can be carried out in the BMW algebra in the sense that the monomial in $\mathbb{B}(D_n)$ corresponding to $a$ can be rewritten as a linear combination of monomials all of which are represented by words of height less than or equal to the height of $a$, with equality occurring for at most one term (see Proposition 3.5(ii)). We exhibit a finite set of reduced words to which each word reduces; see Corollary 6.12. This will lead to a set $T$ of reduced words such that every word in the generators of $\mathbb{B}(D_n)$ can be reduced to an element of $T$ up to multiples by powers of $\delta$. The above argument will give that, when viewed as elements of $\mathbb{B}(D_n)$, the set $T$ is a spanning set of $\mathbb{B}(D_n)$.

In Section 7 we prove our main result by constructing a suitable set $T$ of monomials corresponding to specific triples consisting of pairs of sets of mutually orthogonal roots and a Weyl group element. We also prove Corollary 6.12 by showing that the generalized Temperley–Lieb algebra of type $D_n$, embeds in $\mathbb{B}(D_n)$ and in $\mathbb{B}(D_n')$.

In Section 8 we show that if the ring of coefficients is extended to an integral domain containing $2^{-1}$, the algebra $\mathbb{B}(D_n)$ is cellular in the sense of [16, Definition 1.1]. In our proof, we need the ring extension in order to invoke [14, Theorem 1.1] where cellularity of the Hecke algebras of type $D_n$ is proved for such rings of coefficients. This Hecke algebra is a natural quotient of $\mathbb{B}(D_n)$ and the Hecke algebras of type $D_n−2t$ occur as subalgebras with different idempotents as identities in the analysis. We have applied the above results in [7], where a tangle algebra $\mathbf{KT}(D_n)$ over $R$ on $n$ strands was introduced. This algebra was shown to be a homomorphic image of the BMW algebra $\mathbb{B}(D_n)$ of type $D_n$ and Theorem 1.1 gives that $\mathbf{KT}(D_n)$ is an isomorphic image of it.

Part of the work reported here grew out of the PhD. thesis of one of us, [13]. The other two authors wish to acknowledge Caltech and Technische Universität Eindhoven for enabling mutual visits.

3. BMW and Brauer Algebras

The BMW algebras of type $A_n$ ($n \geq 1$), $D_n$ ($n \geq 4$), and $E_n$ ($n = 6, 7, 8$) have been discussed extensively in [5]. We assume that $M$ is a Coxeter diagram which is one of these (in particular, it has no multiple bonds). Our main results will only concern $M$ of type $A_{n-1}$ and $D_n$. The BMW algebra of type $M$ is defined over the ring $R = \mathbb{Z}[l^{\pm 1}, m, \delta^{\pm 1}]/(m(\delta - 1) - (l^{1} - l))$. 
Definition 3.1. The BMW algebra \( B(M) \) of type \( M \) is the free algebra over \( R \) given by generators \( g_i, e_i \) with \( i \) running over the nodes of the diagram \( M \), subject to the relations in the BMW Relations Table \( \[1 \] \) where \( i \sim j \) denotes adjacency of two nodes \( i \) and \( j \).

Table 1. BMW Relations

Remark 3.2. The set of relations given is redundant. In fact, the relations (HNrer), (HNree), (HNeer), (HTeree), and (RTeree) follow from the others, as we will explain. Moreover, if \( B(M) \) is tensored with a ring in which \( m \) is invertible, they all follow from (RSrr), (RSre), (HCrr), (HNrrr), and (RNre). This is shown in [5] where these were labeled (D1), (R1), (B1), (B2), and (R2), respectively. We will prove the stated redundancies, starting with (HNnee). By (RNre), (RSre), and (RNre), respectively, we have

\[
e_i e_i e_i = e_i g_j g_i e_i = l^{-1} e_i g_i e_i = e_i.
\]

For (HNeer) we multiply (RNre) from the right by \( g_j \), apply (RSrr) to the right hand side, and, for the final equality, (RNre), and (RNre):

\[
e_j e_j g_j = e_j g_j^2 = e_j g_j (1 - mg_j + ml^{-1}e_j) = e_j g_i - me_j g_i g_j + ml^{-1}e_j g_i e_j
\]

\[
= e_j g_i - me_j e_i + me_j.
\]

(HNree) is derived in a similar way. The equation (HNrer) is dealt with in [5, Proposition 2.3] by use of the relations we have obtained. For (HTeree), we use
Recall here that $i \not= k$ because the diagram $M$ has no triangles. For (RTerre) write $e_j g_i g_k e_j = e_j g_i g_j g_i^{-1} g_k e_j$ and use the expression $g_j^{-1} = g_j + m - m e_j$ which follows from (RSrr) and is given in [5, Proposition 2.1].

**Definitions 3.3.** Let $M$ be a graph of type ADE. We define the Brauer monoid $\text{BrM}(M)$ to be the monoid generated by the elements $r_i$ and $e_i$ ($i \in M$) and $\delta$ subject to the relations in the Brauer Relations Table 2. The Brauer algebra of type $M$ is the monoid algebra $\mathbb{Z}[\text{BrM}(M)]$.

Table 2. Brauer Relations

The $r_i$ in $\text{BrM}(M)$ generate a subgroup of the Brauer monoid that we denote $W$. This is a Coxeter group of type $M$ as the $r_i$ satisfy the required relations and, after factoring out the ideal of $\text{Br}(M)$ generated by the $e_i$, we obtain the group algebra of $W$ over $\mathbb{Z}[\delta^{\pm 1}]$.

We consider the Brauer algebra of type $M$ as an algebra over $\mathbb{Z}[\delta^{\pm 1}]$. Here $\delta$ is in the center of $\text{BrM}(M)$ and we identify this $\delta$ with the $\delta$ in $\mathbb{Z}[\delta^{\pm 1}]$. Since the other defining relations of the Brauer monoid are the defining relations of the corresponding BMW algebra $B(M)$ modulo the ideal $(l-1, m)$ generated by $l-1$ and $m$, the Brauer algebra $\text{Br}(M)$ can be identified with $B(M) \otimes_R R/(l-1, m)$. The corresponding equivariant map $a \mapsto a \otimes 1$ will be denoted by $\mu$.

Just as for $B(M)$, some of the relations in the Brauer Relations Table 2 are redundant; see [4, Lemma 3.1]. We will need to rewrite words in the generators $r_i$ and $e_i$, with $\delta^{\pm 1}$ viewed as coefficients. This necessitates the extra relations that are displayed in Table 2.

**Definitions 3.4.** By $F_n$, we denote the monoid that is the central product of the free monoid on the symbols $r_i, e_i$ ($i = 1, \ldots, n$) with the infinite cyclic group generated
by $\delta$. Its elements will be called words. There is a surjective homomorphism of monoids $\pi : F_n \to \text{BrM}(M)$ mapping the symbols $r_i$, $e_i$, and $\delta$ to the corresponding elements of BrM($M$). The monomial in $B(M)$ corresponding to $a \in F_n$ is obtained by replacing $r_i$ by $g_i$ and leaving $e_i$ and $\delta$ as before, so $\mu(\rho(a)) = \pi(a)$. A word $a \in F_n$ is said to be of \textit{height} $t$ if the number of $r_i$ occurring in it is equal to $t$; we denote this number $t$ by $ht(a)$.

We say that $a$ is \textit{reducible} to another word $b$, or that $b$ is a \textit{reduction} of $a$, if $b$ can be obtained by a finite sequence of specified rewrites, listed in the Brauer Relations Table 2, starting from $a$, that do not increase the height. We call a word in $F_n$ \textit{reduced} if it cannot be further reduced to a word of smaller height. We have labeled the relations in the tables above with R or H according to whether the rewrite from left to right strictly lowers the height or not. If the number stays the same, we call it H for homogeneous. Our rewrite system will be the set of all rewrites in the Brauer Relations Table 2 in either direction in the homogeneous case when an H appears in its label and from left to right only in case an R occurs in its label. We write $a \rightsquigarrow b$ if $a$ can be reduced to $b$; for example (RNerr) gives $e_2r_3e_2 \rightsquigarrow e_2$ if $2 \sim 3$. If the height does not decrease during a reduction, we sometimes use the term homogeneous reduction and write $a \rightsquigarrow b$; for example, (HNeee) gives $e_2 \rightsquigarrow e_2e_3e_2$ if $2 \sim 3$. If it does decrease, we also speak of a strict reduction.

Homogeneous reduction induces a congruence relation on $F_n$, to which we will refer as homogeneous equivalence. We denote its set of equivalence classes by $F_n/\rightsquigarrow$.

The congruence property turns it into a monoid.

The reductions in $F_n$ are important because they have a meaning for both the Brauer algebra and the corresponding BMW algebra. For each of the relations in the Brauer Relations Table 2 there is a corresponding relation in the BMW Relations Table 1. In Section 7, the following proposition will be used to find a basis of $B(D_n)$ that has the same size as a basis of $Br(D_n)$.

**Proposition 3.5.** Suppose $a \rightsquigarrow b$ with $a, b \in F_n$.

(i) $\pi(a) = \pi(b)$ in $\text{BrM}(M)$.

(ii) There are a finite number of $\lambda_c \in R$ such that, in $B(M)$,

$$\rho(a) = \rho(b) + \sum_{c \in F_n, \, ht(a) < ht(b)} m\lambda_c \rho(c).$$

**Proof.** (i). For each reduction step of the sequence of relations, the word evaluated in BrM($M$) is the same because the relations are satisfied in BrM($M$) by definition. This means $\pi(a) = \pi(b)$, proving (i).

(ii). The expressions in the BMW Relations Table 1 all have one term on each side whose coefficient is not a multiple of $m$. These terms are the same as in the Brauer Relations Table 2 with $g_l$ instead of $r_l$. Indeed, if $l = 1$ and the terms with coefficient $m$ are ignored, the tables are the same. Each reduction step in $a \rightsquigarrow b$ replaces the term on the left with the corresponding one on the right side of the equality in the table plus terms that are multiples of $m$ and have strictly smaller height. The end result is $\rho(b)$ plus terms that are multiples of $m$, whose height has been reduced at least once. As $a \rightsquigarrow b$ involves only a finite sequence of specific rewrites from Table 2 only a finite number of substitutions from Table 1 has been
applied, and so only a finite number of summands occurs at the right hand side of the equality in (ii).

For \( x_1, \ldots, x_q \in \{r_1, \ldots, r_n, e_1, \ldots, e_n, \delta^{\pm 1}\} \), we write \((x_1 \cdots x_q)^{\text{op}} = x_q \cdots x_1\), thus defining an opposition map on \( F_n \). This notation is compatible with the maps \( \pi \) and \( \rho \) when \( \cdot \)\text{op} on \( B(M) \) and \( Br(M) \) is interpreted as the anti-involution of \([5\text{ Remark 2.1(i)}]\) and \([4\text{ Remark 5.7}]\), respectively.

To end this section, we discuss properties of \( R \) which show how to relate some properties of sets of monomials in \( B(D_n) \) to corresponding ones in \( Br(D_n) \) using the maps \( \pi \) and \( \rho \).

**Lemma 3.7.** The ring \( R \) embeds in \( \mathbb{Q}(\delta)[l^{\pm 1}] \) and also in \( \mathbb{Q}(l, \delta) \).

**Proof.** Let \( D = \mathbb{Z}[l^{\pm 1}, \delta^{\pm 1}] \), which is a unique factorization domain, and let \( F \) be its field of fractions. Put \( s(m) = (1 - \delta)m - (l - l^{-1}) \). Notice \( s(m) \) is primitive and so irreducible in \( F[m] \) by Gauss’ Lemma. Hence \( R = D[m]/(s(m)) \) is an integral domain. Its field of fractions is \( \mathbb{Q}(l, \delta) \). Finally, \( \mathbb{Q}(\delta)[l^{\pm 1}] \) is a subring of \( \mathbb{Q}(l, \delta) \) containing both \( D \) and \( m \), as the latter is equal to \((l - l^{-1})(1 - \delta) \) modulo \( s(m) \), and so also contains \( R \). □

The following lemma will give a lower bound for the rank of \( B(D_n) \).

**Lemma 3.8.** Suppose that \( T \) is a finite set of monomials in \( F_n \) whose images \((\pi(t))_{t \in T}\) are linearly independent in \( Br(D_n) \). Then \((\rho(t))_{t \in T}\) are linearly independent in \( B(D_n) \).

**Proof.** Suppose that \( \sum_{t \in T} \lambda_t \rho(t) \) with \( \lambda_t \in R \) is a non-trivial linear combination that is equal to 0 in \( B(D_n) \). Then the same non-trivial linear relation holds over the principal ideal domain \( \mathbb{Q}(\delta)[l^{\pm 1}] \) into which \( R \) embeds according to Lemma 3.7. Rescale the coefficients by a suitable power of \( l^{-1} \) to guarantee \( \lambda_t \notin (l - 1)(\mathbb{Q}(\delta)[l^{\pm 1}]) \) for some \( s \in T \). Now \( \mu(\lambda_t) \neq 0 \) and \( \pi(t) = \mu(\rho(t)) \) for \( t \in T \) (cf. Definitions 3.4), so \( \sum_{t \in T} \mu(\lambda_t) \pi(t) \) is a non-trivial linear combination in \( Br(D_n) \), that is equal to 0, contradicting the linear independence assumption on \( \pi(t)_{t \in T} \). □

The following result will yield the right upper bound on the rank of \( B(D_n) \).

**Proposition 3.9.** Let \( M \) be of type ADE and let \( T \) be a set of words in \( F_n \) such that the \((\pi(t))_{t \in T}\) is a basis of \( Br(M) \). If each word in \( F_n \) can be reduced to an element of \( \delta^{\pm 2}T \), then \( \rho(T) \) is a basis of \( B(M) \) and each element of \( T \) is a reduced word.

**Proof.** Assume that each word in \( F_n \) can be reduced to an element of \( \delta^{\pm 2}T \). We first prove that \( \rho(T) \) is a linear spanning set of \( B(M) \). If not, there is a word \( a \in F_n \) such that \( \rho(a) \) is not in the linear span of \( \rho(T) \). Pick one of smallest height. Then, by assumption, \( a \sim b \) for some \( b \in \delta^{\pm 2}T \). Proposition 3.8(ii) implies that \( \rho(a) - \rho(b) \) is a linear combination of monomials in \( B(M) \) of height lower than \( s = \lambda t(a) \). If \( s = 0 \), this means \( \rho(a) = \rho(b) \in \delta^{\pm 2}\rho(T) \). Otherwise \( s > 0 \) and we may assume, using induction on height, that monomials in \( B(M) \) of height lower than \( s \) are all in the linear span of the elements in \( \rho(T) \) of height lower than \( s \). Then the right
hand side in the expression of \( \rho(\mathbf{a}) - \rho(\mathbf{b}) \) as a linear combination of monomials of lower height is in the linear span of \( \rho(T) \). Consequently, \( \rho(\mathbf{a}) \) is in the same linear span, a contradiction. We have shown that \( B(M) \) is spanned by \( \rho(T) \).

It now follows from Lemma 3.8 that \( (\rho(t))_{t \in T} \) is a basis of \( B(D_n) \). If \( \mathbf{a} \in T \) is not reduced, then there is \( \mathbf{b} \in F_n \) with \( \mathbf{a} \to \mathbf{b} \) and \( \text{ht}(\mathbf{a}) > \text{ht}(\mathbf{b}) \). After applying the assumption to \( \mathbf{b} \), we may assume \( \mathbf{b} \in \delta^2 T \) and still \( \text{ht}(\mathbf{a}) > \text{ht}(\mathbf{b}) \). In view of the hypothesis, \( \pi(\mathbf{a}) \) and \( \delta^i \pi(\mathbf{b}) \) for some \( i \in \mathbb{Z} \) are distinct members of a basis of \( \text{Br}(D_n) \), so \( \pi(\mathbf{a}) \) and \( \pi(\mathbf{b}) \) are linearly independent. On the other hand, by Proposition 6.3(i), \( \pi(\mathbf{a}) = \pi(\mathbf{b}) \), a contradiction. \( \square \)

4. Admissible Sets and the Function Monoid

Let \( n \in \mathbb{N} \), \( n \geq 4 \). We summarize some of the results of [4] and [6] about admissible sets with a special focus on type \( M = D_n \). These are particular sets of mutually orthogonal positive roots. The results will be used to monitor the reduction of words in \( F_n \). We will fix a root system \( \Phi \) for \( W \) and a set of simple roots \( \alpha_1, \ldots, \alpha_n \) with indices for \( M = D_n \) as indicated in the Dynkin diagram of Figure 1.

![Figure 1. The diagram of type D_n with node labels](image)

In terms of the standard orthonormal basis \( \varepsilon_1, \ldots, \varepsilon_n \) of \( \mathbb{R}^n \), these simple roots are \( \alpha_1 = \varepsilon_1 + \varepsilon_2, \alpha_2 = \varepsilon_2 - \varepsilon_1, \alpha_3 = \varepsilon_3 - \varepsilon_2, \ldots, \alpha_n = \varepsilon_n - \varepsilon_{n-1} \). Accordingly, we will write \( \Phi^+ = (\mathbb{Z}_{\geq 0} \alpha_1 + \mathbb{Z}_{\geq 0} \alpha_2 + \cdots + \mathbb{Z}_{\geq 0} \alpha_n) \cap \Phi \) where \( \mathbb{Z}_{\geq 0} \) are the non-negative integers. The elements of \( \Phi^+ \) are called the positive roots of \( \Phi \) (or simply \( D_n \)); they are of the form \( \varepsilon_j - \varepsilon_i \) and \( \varepsilon_i + \varepsilon_j \) for \( n \geq j > i \geq 1 \). Recall \( \Phi = \Phi^+ \cup (-\Phi^+) \). The reflection in \( \mathbb{R}^n \) with root \( \beta \) is denoted \( r_\beta \). The map \( r_i \mapsto r_\alpha_i \) \((i = 1, \ldots, n)\) extends to an isomorphism from \( W \) to a reflection subgroup of the orthogonal group on \( \mathbb{R}^n \).

We often identify \( W \) with this reflection group by means of the isomorphism.

There are some standard properties of the root systems we are using which we mention here for convenience. All roots have square norm 2. The inner products are all \( \pm 2, \pm 1, \) or 0. If \( (\beta, \gamma) = 1 \), then \( \beta - \gamma \) is a root, and if \( (\beta, \gamma) = -1 \), then \( \beta + \gamma \) is a root, equal to \( r_\beta r_\gamma \). Further if \( (\beta, \gamma) = 0 \), then \( \beta \pm \gamma \) is never a root.

We often encounter the situation in which \( (\beta, \alpha_i) = 0 \), \( i \sim j \), and \( \beta - \alpha_j \) is a root. Then \( (\beta - \alpha_j, \alpha_i) = 1 \) and so \( \beta - \alpha_j - \alpha_i = r_i r_j \beta \) is also a root.

**Remark 4.1.** There are two notions of height. The first is \( \text{ht}(\mathbf{a}) \) for \( \mathbf{a} \) an element of \( F_n \) (cf. Definitions 3.3). The second is the more standard notion of height of a positive root \( \beta \). This is \( \sum \lambda_i \) for the root \( \sum \lambda_i \alpha_i \) where the \( \alpha_i \) are the simple roots. We also denote this \( \text{ht}(\beta) \) and trust no confusion will arise.

In order to recognize the elements of the ideal in \( \text{Br}(D_n) \) generated by \( e_1 e_2 \), see Definition 6.3 we will need the notion of orthogonal mates.
Definitions 4.2. For \( \beta = \varepsilon_i - \varepsilon_j \) a root in the root system \( \Phi \) of type \( D_n \) embedded in \( \mathbb{R}^n \) as indicated above, its orthogonal mate is defined to be \( \beta^* = \varepsilon_i + \varepsilon_j \) and, vice versa, the orthogonal mate of \( \beta^* \) is \( \beta^{**} = \beta \). Furthermore, we write \( r_i^* \) for \( r_{\beta^*} \), the reflection whose root is the orthogonal mate of \( \beta \). For the simple roots \( \alpha_i \), we also write \( r_i^* \) instead of \( r_{\alpha_i}^* \).

If \( n > 4 \), the roots orthogonal to \( \beta \) form a subsystem of \( \Phi \) of type \( A_1D_{n-2} \) and \( \beta^* \) is the unique positive root in the \( A_1 \) component of this subsystem. If \( n = 4 \), the choice of orthogonal mate essentially depends on the choice of an orthogonal pair of simple roots.

There are several equivalent definitions of admissible sets as outlined in [6, Proposition 2.3]. For our purposes we may define a set \( B \) of mutually orthogonal positive roots to be admissible if and only if, when \( \alpha_1, \alpha_2, \alpha_3 \in B \) and there exists a root \( \alpha \) for which \( (\alpha_i, \alpha) = \pm 1 \) for all \( i \), then \( r_{\alpha_1}\alpha_1, r_{\alpha_2}\alpha_2, r_{\alpha_3}\alpha_3 \alpha \) or \( -r_{\alpha_1}\alpha_1, r_{\alpha_2}\alpha_2, r_{\alpha_3}\alpha_3 \alpha \) is also in \( B \).

Given any set, \( B \), of mutually orthogonal positive roots, a straightforward exercise shows there is a unique smallest admissible set containing \( B \). This set is called the admissible closure of \( B \), notation \( B^\text{cl} \); see [4, Definition 2.2].

By \( A \) we denote the collection of all admissible sets (including the empty set). This set has a natural \( W \)-action given by

\[
wB = \Phi^+ \cap \{ \pm w \beta \mid \beta \in B \}
\]

for \( w \in W \). A representative of each \( W \)-orbit in \( A \) is given in [3, Table 3]; this is a corrected version of a similar table in [6]. We will need these only for types \( A_n \) and \( D_n \), which, for the convenience of the reader, are summarized in Lemma 4.3 and Table 3. The meaning of \( M_Y \) and \( S_Y \) in Table 3 will become clear later (in Proposition 5.8).

Notation 4.3. By \( \mathcal{Y} \) we denote the collection of the following sets of nodes of \( D_n \).

\[
\begin{align*}
Y(t) &= \{n, n-2, \ldots, n-2t+2\}, \text{ for } t \in [0, \lfloor n/2 \rfloor] \\
Y^*(t) &= \{n, n-2, \ldots, n-2t+4, 1, 2\}, \text{ for } t \in [1, \lfloor n/2 \rfloor] \\
Y'(n/2) &= \{1, 4, 6, 8, \ldots, n\} \text{ if } n \text{ is even.}
\end{align*}
\]

For \( Y \in \mathcal{Y} \), the set \( B_Y \) is the admissible closure of the set of roots \( \alpha_j \) for \( j \in Y \). For \( Y = Y^*(t) \), this implies that \( B_Y \) is the set of roots \( \alpha_j \) and \( \alpha_j^* \) for \( j \in Y \). For \( Y = Y(t) \) or \( Y'(n/2) \) however, no orthogonal mates occur and so \( B_Y \) is the set of roots \( \alpha_j \) for \( j \in Y \).

Lemma 4.4. Each \( W \)-orbit in \( A \) has a unique representative \( B_Y \) for \( Y \in \mathcal{Y} \).

For instance, if \( n = 4 \), there are three orbits of admissible sets of size 2, with representatives \( B_Y \), where \( Y = Y(2) \), \( Y'(2) \), and \( Y^*(1) \), respectively.

Notice that, if \( B \) is an admissible set containing a root as well as its orthogonal mate, then it is a union of roots together with their orthogonal mates.

The following proposition is proved in [4, Theorem 3.6]; the fact that \( e_i B \) as described below is well defined is shown in [4, Lemma 3.3(v)].

Proposition 4.5. Let \( M \) be of type ADE. The action of \( W \) on \( A \) extends to an action of the Brauer monoid \( \text{Br}(M) \) determined by the following rules for the
We will use the action of Proposition 4.5. Let $\mathcal{Y}$ be a word in $F_n$.

Our immediate goal will be to show that $\mathcal{Y}$ can be rewritten to a reduced word that is uniquely determined by $\pi(\mathcal{Y})$ up to homogeneous equivalence, so the reduced
word will be a unique element of $F_n$. In fact, we shall be working with words in $F_n$ but often think of them as representing classes in $F_n$. Later, in Sections 7 and 8, we will use words in $F_n$ to represent monomials in $B(D_n)$.

Before we continue we introduce some notation.

**Notation 5.1.** Suppose that $k$ and $i$ are two nodes of $D_n$. Let $i = i_1, i_2, \ldots, i_r = k$ be the geodesic path from $i$ to $k$ in $D_n$. Then we set $e_{i,k} = e_{i_1}e_{i_2} \cdots e_{i_r}$, which we interpret as an element of $F_n$. Notice the first factor is $e_i$ and the last is $e_k$. In particular, for $i < k$ and $k \geq 3$, we have $e_{i,k} = e_ie_{i+1} \cdots e_k$ unless $i = 1$ in which case it is $e_1e_3e_4 \cdots e_k$. Also $e_{1,2} = e_1e_3e_2$ is a special case.

Let $\beta$ be a positive root. If $\beta = \sum \lambda_i \alpha_i$ we call the support of $\beta$ the set of nodes $i$ for which $\lambda_i \neq 0$; it is denoted $\text{Supp}(\beta)$. As in [5], we will write, if $k$ is a node of the diagram, $\text{Proj}(k, \beta)$ for the node of $D_n$ in $\text{Supp}(\beta)$ nearest to $k$. There is a unique one as the support is a connected set of nodes in the Dynkin diagram $D_n$, which is a tree.

**Definition 5.2.** If $k \in \text{Supp}(\beta)$, then, as follows directly from [5] Proposition 3.2], there is a unique Weyl group element $a_{\beta,k}$ of smallest length that maps $\{\alpha_k\}$ to $\{\beta\}$ in the action of Proposition 4.3 (so $a_{\beta,k}\{\alpha_k\} = \{\beta\}$). Its height, as a monomial of $\text{Br}(D_n)$, is equal to $\text{ht}(\beta) - 1$. The opposite element $a_{\beta,k}^0$ maps $\{\alpha_k\}$ to $\{\alpha_1\}$. We will often view $a_{\beta,k}$ as an element of $F_n$ in the guise of a shortest expression for $a_{\beta,k}$ as a product of simple reflections. Since any two such expressions are homogeneously equivalent, they represent the same element of $F_n$, which suffices for our purpose of reductions.

We extend the definition of $a_{\beta,k}$ to the case where $k \notin \text{Supp}(\beta)$. For $\beta$ a positive root with $k \notin \text{Supp}(\beta)$ and $k'$ the node next to $k$ on the geodesic path from $k$ to $j = \text{Proj}(k, \beta)$, we set $a_{\beta,k} = a_{\beta,j}e_{j,k'}$ in $F_n$.

We will be mainly concerned with the case $k = n$.

**Lemma 5.3.** The elements $a_{\beta,n}$ satisfy the following properties.

(i) If $j \leq n - 1$, then $a_{\alpha_j,n}e_n = e_{j,n}$.

(ii) If $j$ is a node of $D_n$ such that $\beta - \alpha_j$ is a root, then $a_{\beta,n}e_n \leftrightarrow r_j a_{\beta - \alpha_j,n}e_n$.

(iii) $\text{ht}(a_{\beta,n}) = \text{ht}(\beta) - 1$.

**Proof.** (i). Clearly $n$ is not in the support of $\alpha_j$ and so $a_{\alpha_j,n} = e_{j,n}$. The required equality follows from multiplication by $e_n$ on the right.

(ii). We first consider the case where $n \in \text{Supp}(\beta)$. In this case $a_{\beta,n}$ is any word of shortest length which takes $\alpha_n$ to $\beta$. Its length is $\text{ht}(\beta) - 1$. As mentioned above and in [5] Proposition 2.3] it is a unique up to homogeneous equivalence. If $j \neq n$, then $a_{\beta - \alpha_j,n}$ is a word of shortest length taking $\alpha_n$ to $\beta - \alpha_j$ and so $r_j a_{\beta - \alpha_j,n}$ is a word of shortest length taking $\alpha_n$ to $\beta$, proving that $a_{\beta,n} \leftrightarrow r_j a_{\beta - \alpha_j,n}$, and so $a_{\beta,n}e_n \leftrightarrow r_j a_{\beta - \alpha_j,n}e_n$.

If $j = n$, then $\beta - \alpha_n$ is a root. Because of the structure of the roots of $D_n$, this means the coefficient in $\beta$ of both $\alpha_n$ and $\alpha_{n-1}$ as a linear combination of simple roots is 1 and so $\beta - \alpha_n$ has $n - 1$ in its support but not $n$. In particular, $a_{\beta - \alpha_n,n-1}$ is a word of height $\text{ht}(\beta) - 1$ taking $\alpha_n$ to $\beta - \alpha_n$. As $n$ is not in the support of $\beta - \alpha_n$ but $n - 1$ is, $a_{\beta - \alpha_n,n-1}$ is a word in $r_i$ with $i \leq n - 1$ and further as the coefficient of $\alpha_n$ in $\beta - \alpha_n$ is just 1, all the $r_i$ occurring in a reduced word for $a_{\beta - \alpha_n,n-1}$ have $i \leq n-2$. In particular $r_n$ and $a_{\beta - \alpha_n,n-1}$ commute. Also, $a_{\beta - \alpha_n,n} = a_{\beta - \alpha_n,n-1}e_{n-1}$
by definition. Now \( r_n a_{\beta - \alpha_n, n} e_n = r_n a_{\beta - \alpha_n, n} e_{n-1} e_n \overset{\text{HNree}}{\sim} a_{\beta - \alpha_n, n-1} r_n e_{n-1} e_n \). By (HNree) \( r_n e_{n-1} e_n \overset{\text{HNree}}{\sim} r_{n-1} e_n \). In terms of the action of Proposition 4.3, this implies \( a_{\beta - \alpha_n, n-1} e_{n-1} \{ \alpha_n \} = a_{\beta - \alpha_n, n-1} \{ \alpha_{n-1} + \alpha_n \} \). Recall \( a_{\beta - \alpha_n, n-1} \) is a shortest word in \( r_1, \ldots, r_{n-1} \) taking \( \{ \alpha_{n-1} \} \) to \( \{ \beta - \alpha_n \} \) and so is a word of shortest length taking \( \{ \alpha_{n-1} + \alpha_n \} \) to \( \{ \beta \} \) as \( a_{\beta - \alpha_n, n-1} \) fixes \( \{ \alpha_n \} \). Now \( a_{\beta - \alpha_n, n-1} r_{n-1} \) is a shortest word taking \( \{ \alpha_n \} \) to \( \{ \beta \} \) and so \( a_{\beta - \alpha_n, n-1} r_{n-1} \overset{\text{HNree}}{\sim} \alpha_{\beta, n} \). This gives \( r_n a_{\beta - \alpha_n, n} e_n \overset{\text{HNree}}{\sim} a_{\beta - \alpha_n, n-1} r_{n-1} e_n \overset{\text{HNree}}{\sim} \alpha_{\beta, n} e_n \).

If \( n \not\in \text{Supp}(\beta) \), let \( i = \text{Proj}(\beta, n) \). If \( i > 3 \), the argument above applies directly with \( i \) instead of \( n \) and \( j \leq i \), giving \( r_j a_{\beta - \alpha_j, i} e_i \overset{\text{HNree}}{\sim} \alpha_{\beta, j} e_i \). The assertion now follows from right multiplication by \( e_{i+1} \). For \( i = 3 \), the root \( \beta \) is \( \alpha_3 + \alpha_2 \) or \( \alpha_3 + \alpha_1 \) and the arguments are similar. Notice \( i \) cannot be 1 or 2 as \( \beta - \alpha_j \) is a root.

(iii). This is direct from (ii) and the definition of \( a_{\beta, n} \).

Remark 5.4. As the proof uses the relation (HNree) which is not binomial in the BMW algebra, two homogeneously equivalent words of (ii) do not necessarily have the same image under \( \rho \) in the BMW algebra. Indeed, if \( j = n \) and \( \beta = \alpha_{n-1} + \alpha_n \), then \( a_{\beta, n} = r_{n-1} \) and \( a_{\beta - \alpha_n, n} = e_{n-1} \), so \( \rho(a_{\beta, n} e_n) = g_{n-1} e_n \) is distinct from \( \rho(r_n a_{\beta - \alpha_n, n} e_n) = g_n e_{n-1} e_n \). As indicated in Proposition 3.3, the two expressions are equal up to sums of monomials of lower height (with coefficients in the ideal generated by \( m \)).

We have denoted words in \( F_n \) by underlined symbols like \( \alpha \). In the remainder of the paper we will need to reduce words which have specific \( r_i \) or \( e_i \) in them. It is notionally awkward to have long strings underlined, and so we will dispense with this for words including such \( r_i \) and \( e_i \). For example we write \( \alpha r_i r_j e_i \sim \alpha e_j e_i \) rather than \( \alpha r_i r_j e_i \sim \alpha e_j e_i \). We continue to underline general elements of \( F_n \) as \( \alpha \).

Let \( M \) be a Coxeter diagram with \( n \) nodes. The Matsumoto–Tits rewrite rules of type \( M \) on \( s_1, \ldots, s_k \) are the following rewrite rules in the free monoid on \( s_1, \ldots, s_n \).

\[
\begin{align*}
s_i s_i & \sim 1 \\
s_i s_j & \sim s_j s_i \text{ if } i \neq j \\
s_i s_j s_i & \sim s_j s_i s_j \text{ if } i \sim j
\end{align*}
\]

Note that the second and the third rule are homogeneous.

Lemma 5.5. Let \( M \) be a Coxeter diagram with \( n \) nodes. Then any two reduced words with respect to the Matsumoto–Tits rewrite rules of type \( M \) on \( s_1, \ldots, s_n \) are homogeneously equivalent, that is, can be rewritten into each other by means of a series of the second and the third rewrite rules.

Proof. The result can be found in [27] and is independently proved in [22]. A more general version is found in [3].

As a first application, note that, for the subgroup \( W \) of \( \text{BrM}(D_n) \), the rewrite rules with \( r_1, \ldots, r_n \) instead of \( s_1, \ldots, s_k \) coincide with (RSrr), (HCr), and (HNrrr) of Table 2. Therefore, each element of \( W \) corresponds to a unique reduced word of \( F_n \) up to homogeneous equivalence. In other words, the equivalence classes in \( F_n \)
of reduced words over \( \{r_1, \ldots, r_n\} \) correspond bijectively with the elements of the Coxeter group \( W \). This implies that, for each reduced word \( \bar{a} \in F_n \) all of whose symbols are in \( \{r_1, \ldots, r_n\} \), its homogeneous equivalence class is uniquely determined by \( \pi(a) \). In Proposition 5.8 we will generalize this application to recognize Coxeter groups of type \( M_Y \) for each \( Y \in \mathcal{Y} \), using words \( \bar{a} \) in \( F_n \) to be specified in Notation 5.7.

A slightly less general statement holds for \( B(D_n) \) instead of \( BrM(D_n) \). As of the above-mentioned rewrite rules, \((HCrr)\) and \((HNrr)\) are binomial in Table II as well, for each reduced \( \bar{a} \in F_n \) all of whose symbols are in \( \{r_1, \ldots, r_n\} \), its homogeneous equivalence class is uniquely determined by \( \rho(\bar{a}) \) as well. In Proposition 8.4, we will generalize this application, using the same words \( \bar{a} \) as above in \( F_n \), to recognize subquotients of \( B(D_n) \) isomorphic to Hecke algebras of type \( M_Y \) for \( Y \in \mathcal{Y} \).

Observe that \( F_{n-1} \) is a submonoid of \( F_n \).

**Lemma 5.6.** Let \( \bar{z}^* = e_{n,2}r_1e_{3,n} \) for \( n \geq 3 \), \( \bar{z}^*_1 = r_2e_1 \), and \( \bar{z}^*_2 = r_1e_2 \) all of these viewed as words in \( F_n \). Then \( \bar{z}^*_1 \) has height 1 and occurs in the following reductions for \( n \geq 3 \).

(i) \( r_n^* e_n \leadsto \bar{z}^*_1 \) and \( e_n r_n^* \leadsto \bar{z}^*_1 \).

(ii) \( \bar{z}^*_1 \leadsto e_n,3 r_2 e_1 e_{3,n} \).

(iii) For \( n \geq 4 \) and \( i \in \{1, \ldots, n-2\} \), \( e_i \bar{z}^*_1 \leadsto e_n \bar{z}^*_1 \leadsto e_n \bar{z}^*_2 \) and \( r_i \bar{z}^*_2 \leadsto \bar{z}^*_2 r_i \).

(iv) \( \bar{z}^*_1 e_{n-2} \leadsto e_n \bar{z}^*_1 \) and \( e_n \bar{z}^*_1 \leadsto e_n \bar{z}^*_2 \).

(v) \( \bar{z}^*_2 \leadsto e_n \).

For \( n \) equal to 1 or 2, statements (i) and (v) also hold.

**Proof.** Assume first \( n \geq 3 \). By definition, there is only one factor \( r_i \) in \( \bar{z}^*_1 \) and so its height is at most 1.

To see that it does not have height zero we use the representation \( \rho_Y(\{\alpha_n\}) \) of \( \text{[4]} \) Theorem 3.6. In particular we are considering \( Y(1) = \{\alpha_n\} \). Consider the action of \( \bar{z}^*_1 \) in the notation of [loc. cit.] on the 1-space spanned by the vector \( \xi_{\{\alpha_n\}} \). Indeed \( e_2 \xi_{\{\alpha_n\}} = \delta_{\{\alpha_n\}} \) and then \( r_1 \xi_{\{\alpha_n\}} = \xi_{\{\alpha_n\}} r_1 \). It follows from [loc. cit.] that \( h_{1,\alpha_2} \) is the Weyl group of \( A_1 \) in the notation of Proposition 5.8, \( \bar{z}^*_1 \xi_{\{\alpha_n\}} = \delta_{\{\alpha_n\}} h_{1,\alpha_2} \). If \( \bar{z}^*_1 \) could be reduced it would have height 0 and the action on \( \xi_{\{\alpha_n\}} \) would either be 0 or would be \( \xi_{\{\beta\}} \delta^k \) for \( \beta \) a root and for some \( k \) a contradiction. This means \( \bar{z}^*_1 \) has height 1.

(i) Let \( w_{2,n} = r_3 r_2 r_4 r_3 r_5 r_4 \cdots r_{n-1} r_n r_{n-2} r_{n-1} \) be as in [5] Lemma 3.1 and set \( w_{n,2} = w_{2,n}^{op} \). Then \( r_n^* \bar{z}^*_1 = w_{n,2} r_1 w_{2,n} \) where \( r_n^* \) was defined in Definition 4.2. In order to show the required reductions, we use repeatedly the reducing relation (RNrr), that is, \( r_j r_i e_j \leadsto e_i e_j \) for \( i \sim j \). In particular, \( w_{n,2} e_n \leadsto e_{2,n} \). Now \( r_1 e_{2,n} \leadsto e_2 r_1 e_{3,n} \) and \( r_n^* e_n \leadsto w_{n,2} r_1 w_{2,n} e_n \leadsto e_n r_1 e_{3,n} = \bar{z}^*_1 \). A similar computation shows that \( e_n r_n^* \leadsto \bar{z}^*_2 \).

(ii) This statement holds because of \( e_3 e_2 r_1 e_3 \leadsto e_3 r_2 e_1 e_3 \), which is immediate from the defining relation (HTeere).

(iii) For \( i \in \{2, \ldots, n-2\} \), by the definition of \( e_{k,n} \), \( \text{(HCce)} \), and \( \text{(HNnee)} \),

\[ e_i \bar{z}^*_1 \leadsto e_{n,i+2} e_i e_{i+1} e_{i+1} e_2 r_1 e_{3,n} \leadsto e_{n,i+2} e_i e_{3,n} \]
\[ \leadsto e_{n,i+2} e_i e_{2,i+2} e_i e_{i+1} e_2 r_1 e_{3,n} \leadsto e_{i+2} r_1 e_{3,i} e_{n,i+2} e_i e_{i+1} e_{i+2,n} \]
\[ \leadsto \bar{z}^*_1 e_n \leadsto e_n \bar{z}^*_2. \]
By (H Cer), (H Ne), and (H Neer),
\[
\begin{align*}
\ell & \leftrightarrow e_{n,i+2}r_i e_{i+1} e_i e_{i-1} e_{i-2} r_i e_i e_{i-2}, \\
\ell & \leftrightarrow e_{n,i+2} e_i e_{i-1} e_{i-2} r_i e_i e_{i-2} e_i e_{i-1}, \\
\ell & \leftrightarrow e_{n,2} r_i e_i e_{i-1} e_{i-2} r_i e_i e_{i-2} e_i e_{i-1}, \\
\ell & \leftrightarrow e_{n,3} r_i e_i e_{i-1} e_{i-2} r_i e_i e_{i-2} e_i e_{i-1} r_i e_i e_{i-2} e_i e_{i-1}.
\end{align*}
\]

The case \( i = 1 \) is notationally different but can be done the same way as \( i = 2 \).

(iv). In view of the palindromic nature of the word \( z_i^n \) and the fact, proved in (iii), that \( z_i^n \) and \( e_n \) commute homogeneously, we see that \( e_i \) and \( z_i^n \) commute homogeneously. Applying this with \( i = n - 2 \) gives \( z_{n-2} \leftrightarrow e_{n} z_{n-2} \). The second chain of homogeneous equivalences is a direct consequence of (RSrr).

(v). By (RS ee), (HC er), (HN ee), and (RS rr),
\[
\begin{align*}
\ell^* & = e_{n,4} e_{3} e_{2} r_1 e_{2} e_{3} e_{4} n e_{n,4} e_{3} e_{2} e_{3} e_{4} n, \\
& \overset{\text{commute}}{\Rightarrow} \delta e_{n,4} e_{3} e_{2} e_{3} e_{4} n \Leftrightarrow \delta e_{n}.
\end{align*}
\]

Also, by (HS ee), (HC er), (HN ee), and (RS rr),
\[
\begin{align*}
\ell^* & = e_{n,4} e_{3} e_{2} r_1 e_{2} e_{3} e_{4} n e_{n,4} e_{3} e_{2} e_{3} e_{4} n, \\
& \overset{\text{commute}}{\Rightarrow} \delta e_{n,4} e_{3} e_{2} e_{3} e_{4} n \Leftrightarrow \delta e_{n}.
\end{align*}
\]

The cases \( n = 1 \) and \( n = 2 \) can be done separately. \( \square \)

**Notation 5.7.** Let \( M \) be of type ADE. For any coclique \( Y \) of \( M \), we write \( e_Y = \prod_{\alpha \in Y} e_\alpha \) and \( \hat{e}_Y = \delta^{-|Y|} \prod_{\alpha \in Y} e_\alpha \). All factors commute, so we need not care about the order in which they occur. For instance \( Y(0) = \emptyset \) and \( \hat{e}_Y(0) = 1 \), whereas \( Y(1) = \{\alpha_n\} \) and \( \hat{e}_Y(1) = \hat{e}_n \).

We distinguish the following elements of \( F_n \) according to the different possibilities for \( Y \in \mathcal{Y} \). We need \( z_n^* \) as in Lemma 5.6 and \( e_n = e_{n,2} e_1 e_{3},n \), which is the height zero analog of \( z_n^* \). The elements \( s_i \) and \( \hat{s}_i \) will play roles reminiscent of \( r_i \) and \( e_i \).

\[
\begin{align*}
Y = Y(t) & \quad (t > 0) \quad : \quad s_0 = \frac{s_n}{\delta} \delta^{-1} \hat{e}_Y, \quad s_i = r_i \hat{e}_Y, \\
& \quad \quad f_0 = \frac{f_n}{\delta} \delta^{-1} \hat{e}_Y, \quad f_i = e_i \hat{e}_Y \quad (1 \leq i \leq n - 2t), \\
Y = Y(0) & \quad : \quad s_i = r_i, \quad f_i = e_i \quad (1 \leq i \leq n),
\end{align*}
\]

\[
\begin{align*}
Y = Y(\frac{n-1}{2}) & \quad (n \text{ odd}) \quad : \quad s_0 = \frac{s_n}{\delta} \delta^{-1} \hat{e}_Y, \quad f_0 = \frac{f_n}{\delta} \delta^{-1} \hat{e}_Y \\
Y = Y(\frac{n}{2}) & \quad (n \text{ even}) \quad : \quad s_i = r_i \delta^{-1} \hat{e}_Y, \quad f_i = \hat{e}_Y \\
Y = Y'(\frac{n}{2}) & \quad (n \text{ even}) \quad : \quad s_i = r_i \delta^{-1} \hat{e}_Y, \quad f_i = \hat{e}_Y \\
Y = Y^*(t) & \quad (t > 0) \quad : \quad s_i = r_i \delta^{-1} \hat{e}_Y, \quad f_i = \hat{e}_Y \quad (1 \leq i \leq n - 2t - 1)
\end{align*}
\]

Let \( Y \in \mathcal{Y} \). The indices \( i \) of \( s_i \) and \( f_i \) occurring in Notation 5.7 are attached to the diagram \( M_Y \) in such a way that \( 0 \) (if it occurs) corresponds to the isolated component \( A_0 \) of \( M_Y \) and the other component (of type A or D) is labeled as usual for A and as indicated in Figure 1 for D. For instance, in case \( Y = Y(t) \) with
In the proposition below we establish the Matsumoto–Tits rewrite rules for the Coxeter group of type $M_Y$ with generators $\pi(s_i)$ as in (5.7) and identity $e_Y$. The $f_s$ will be studied in the next section.

**Proposition 5.8.** Let $n \geq 4$ and $Y \in \sY$. The words $s_i$ in $F_n$, for $i$ a node of $M_Y$, have height 1 and satisfy the following properties.

(i) With respect to the rewrite system of Table 4 in $F_n$, the words $s_i$ satisfy the Matsumoto–Tits rewrite rules of type $M_Y$ with identity element $e_Y$. That is, they satisfy $e_Y s_i e_Y \rightsquigarrow s_i$, $s_i e_Y \rightsquigarrow s_i$, $e_Y s_i \rightsquigarrow s_i$, $s_i s_j \rightsquigarrow s_j s_i$ if $i \neq j$, and $s_i s_i \rightsquigarrow s_i$ if $i \sim j$, where $i$ and $j$ are nodes of $M_Y$.

(ii) The elements $\pi(s_i)$, for $i$ running through the nodes of $M_Y$, generate a Coxeter group of type $M_Y$ in $\text{BrM}(D_n)$ with identity element $\pi(e_Y)$.

(iii) For $Y \in \sY$, denote $U_Y$ the set of words in $F_n e_Y$ that are minimal expressions in the $s_i$ (where $i$ runs over the nodes of $M_Y$) for elements of the Coxeter group of $(ii)$. Then the restriction of $\pi$ to $U_Y$ induces a bijection from the set of homogeneous equivalence classes in $U_Y$ onto this Coxeter group.

**Proof.** Recall $\text{ht}(e_Y) = 0$. By Lemma 5.6(ii), $\text{ht}(z_n) = 1$, so $\text{ht}(<t_0>) = 1$, and, clearly, $\text{ht}(s_i) = 1$ for $i > 0$.

(i). We verify the individual rewrite rules in the case where $Y = Y(t)$ and leave the other cases to the reader (as they are similar or easier). Those involving $e_Y(t)$ at the left hand side are straightforward applications of the rules (HSc), (HCce), (HCRe), and (HNee).

(ii) The fact that the $\pi(s_i)$ for $i \leq n - 2$ generate a quotient of the Coxeter group of type $M_Y(t)$ is immediate from (i) and the fact that a rewrite rule $x \rightsquigarrow y$ in $F_n$ implies $\pi(x) = \pi(y)$. Therefore, it suffices to show that there is a surjective homomorphism from the group generated by the $\pi(s_i)$ onto $W(M_Y(t))$. This follows from [4, Lemma 1.3].

(iii). This is immediate from (ii) and Lemma 5.5. 

\[0 < t < (n - 1)/2, \text{the diagram } M_Y = A_1D_{n-2t} \text{ is labeled as follows.}\]

\[\begin{array}{c}
0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad \cdots \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 2
\end{array}\]

\[\begin{array}{c}
\circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \cdots \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ \quad \circ
\end{array}\]

In the proposition below we establish the Matsumoto–Tits rewrite rules for the Coxeter group of type $M_Y$ with generators $\pi(s)$ as in (5.7) and identity $e_Y$. The $f_s$ will be studied in the next section.

**Proposition 5.8.** Let $n \geq 4$ and $Y \in \sY$. The words $s_i$ in $F_n$, for $i$ a node of $M_Y$, have height 1 and satisfy the following properties.

(i) With respect to the rewrite system of Table 4 in $F_n$, the words $s_i$ satisfy the Matsumoto–Tits rewrite rules of type $M_Y$ with identity element $e_Y$. That is, they satisfy $e_Y s_i e_Y \rightsquigarrow s_i$, $s_i e_Y \rightsquigarrow s_i$, $e_Y s_i \rightsquigarrow s_i$, $s_i s_j \rightsquigarrow s_j s_i$ if $i \neq j$, and $s_i s_i \rightsquigarrow s_i$ if $i \sim j$, where $i$ and $j$ are nodes of $M_Y$.

(ii) The elements $\pi(s_i)$, for $i$ running through the nodes of $M_Y$, generate a Coxeter group of type $M_Y$ in $\text{BrM}(D_n)$ with identity element $\pi(e_Y)$.

(iii) For $Y \in \sY$, denote $U_Y$ the set of words in $F_n e_Y$ that are minimal expressions in the $s_i$ (where $i$ runs over the nodes of $M_Y$) for elements of the Coxeter group of $(ii)$. Then the restriction of $\pi$ to $U_Y$ induces a bijection from the set of homogeneous equivalence classes in $U_Y$ onto this Coxeter group.

**Proof.** Recall $\text{ht}(e_Y) = 0$. By Lemma 5.6(ii), $\text{ht}(z_n) = 1$, so $\text{ht}(<t_0>) = 1$, and, clearly, $\text{ht}(s_i) = 1$ for $i > 0$.

(i). We verify the individual rewrite rules in the case where $Y = Y(t)$ and leave the other cases to the reader (as they are similar or easier). Those involving $e_Y(t)$ at the left hand side are straightforward applications of the rules (HSc), (HCce), (HCRe), and (HNee).

\[s_i s_j \rightsquigarrow e_Y(t).\] By Lemma 5.6(iv) we see $e_n z_n \rightsquigarrow s_n e_n$ and $z_n e_j \rightsquigarrow e_j z_n$ for $j \leq n - 2$ and so $z_n e_Y(t) \rightsquigarrow e_Y(t) z_n$. Hence $z_n$ commutes homogeneously with $e_Y(t)$ and so in the definition of $<t_0>$ it does not matter on which side $e_Y(t)$ occurs. In particular, using Lemma 5.6(v), we find $z_0 z_0 \rightsquigarrow z_0 z_0 e_Y(t) e_Y(t) \delta^{2 - 2t} \rightsquigarrow \delta e_n e_Y(t) \delta^{2 - 2t} \rightsquigarrow e_Y(t) \delta^{-1}$, which is the identity element of $\pi(U_Y(t))$. This settles the case $i = 0$. For $i > 0$, the assertion $s_i s_i \rightsquigarrow e_Y(t)$ follows directly from the fact that $e_Y(t)$ and $e_i$ commute and (HSrr).

\[s_i s_j \rightsquigarrow s_j s_i \text{ if } i \neq j.\] For $i = 0$ and $j > 0$, this follows from Lemma 5.6(iii). For $i > 0$ and $j > 0$, it is immediate from (HCrr).

\[s_i s_j \rightsquigarrow s_i s_j \text{ if } i \sim j.\] Here we must have $i, j > 0$. Now it is immediate from (HNrr).

(ii). The fact that the $\pi(s_i)$ ($0 \leq i \leq n - 2t$) generate a quotient of the Coxeter group of type $M_Y(t)$ is immediate from (i) and the fact that a rewrite rule $x \rightsquigarrow y$ in $F_n$ implies $\pi(x) = \pi(y)$. Therefore, it suffices to show that there is a surjective homomorphism from the group generated by the $\pi(s_i)$ onto $W(M_Y(t))$. This follows from [4, Lemma 1.3].

(iii). This is immediate from (ii) and Lemma 5.5. 

\[\square\]
6. Reduction in the Brauer Monoid

In this section we continue to discuss reductions of words in $F_n$. The main purpose is to show that each word in $F_n$ can be reduced to a particular form described in Theorem 6.11. We first study the product of a generator and a word $a_{β,n}ε_n$, which is in reduced form. Here $a_{β,n}$ is given by Definition 6.2. In the action of Proposition 4.3, the element $π(a_{β,n}ε_n)$ maps $∅$ to $\{β\}$, so after left multiplication by $e_i$ it will map $∅$ to $\{α_i\}$ (or in case $α_i ⊥ β$ to $\{α_i, β\}$, and, after left multiplication with $r_i$, it will map $∅$ to $\{r_iβ\}$. The lemma below will find corresponding reduced words. In order to control the kernel of this action, we need a little more notation.

Notation 6.1. For $Y ∈ Y$, let $Z_Y$ be the subsemigroup of $F_n$ generated by all $δ^je_Y$ for all $j ∈ Z$, and $f_i$ and $f_-$ for all nodes $i$ of $MY$ as in Notation 5.7. We also write $Z_n$ instead of $Z_Y(1)$. The subsemigroup $Z_∅$ coincides with $F_n$.

Lemma 6.2. Let $M = D_n$, let $i ∈ \{1, \ldots, n\}$, and let $β ∈ Φ^+$. Then the word $e_i a_{β,n}ε_n$ reduces to a word in $a_{β,n}Z_n$, where $β'$ is a positive root with $\text{ht}(β') ≤ \text{ht}(β)$. Also, $r_i a_{β,n}ε_n$ can be reduced to a word in $a_{β',n}Z_n$, where $\{β'\} = r_i(β)$. Moreover, if $α ∈ F_n$, then $αε_n$ can be reduced to a word in $a_{β',n}Z_n$, where $β'$ is a positive root with $\text{ht}(β') ≤ \text{ht}(α)$ and $β' ≡ α(α_n)$.

Proof. We proceed by induction on $\text{ht}(β)$. If $\text{ht}(β) = 1$ we have $β = α_j$ for some node $j$ of $D_n$. By Lemma 5.3, $α_{β,n}ε_n ⇝ e_{-i,n}$.

Consider first $e_i a_{β,n}ε_n$. By the above, $e_i a_{β,n}ε_n ⇝ e_i e_{j,n}$. If $\{i, j\} = \{1, 2\}$, then $e_i e_{j,n} = e_1 e_2 ⇝ e_i e_2 + e_2 e_i = e_2 e_i e_2 = a_{β,n}ε_n$. By symmetry of the diagram, the case $j = 1$ can be replaced by $j = 2$ and handled in a similar way, so assume $j ≥ 2$. If $i < j$, then $e_i$ can be commuted to the right and be absorbed into $Z_n$ as $e_{-i,n}$.

If $i = i - 1$, then we may assume $i ≥ 2$ as we already handled the case $\{i, j\} = \{1, 2\}$, and so $e_i a_{β,n}ε_n ⇝ e_i e_{j,n} = e_i e_{i,n} = a_{α_i,n}ε_n$. If $i = j$ we obtain $e_i a_{β,n}ε_n ⇝ e_i β,n e_{-i,n}$. If $i = j + 1$ we can use $e_i e_j e_i ⇝ e_i e_i$, and $e_i a_{β,n}e_n ⇝ e_i e_{i,n}$. Otherwise $i ≠ j$ and $i ≠ j$; commute the $e_i$ past terms in $e_{j,n}$, obtain $e_i a_{β,n}ε_n ⇝ e_i e_{j+1} e_i e_{i-1} e_i e_n$. Now use $e_i e_{i-1} e_i ⇝ e_i$ commute the preceding terms $e_k$ to the right and absorb them into $Z_n$ as products of $e_{-i,n}$. In each of these cases $e_i a_{β,n}ε_n ⇝ a_{β',n}ε_n$ for some $ε_n$ in $Z_n$ and some $β' ∈ \{α_i, α_j\}$ as required.

We now consider $r_i a_{β,n}ε_n$ with $β = α_j$ for some node $j$, where $r_i a_{β,n}ε_n ⇝ r_i e_{j,n}$. There are two special cases which we handle directly. If $j = 2$ with $i = 1$, and $j = 1$ with $i = 2$. For the first we have $r_1 e_{2,n} ⇝ e_2 r_1 e_{2,n} δ^{-1}$. Notice $e_2 ↘ e_{2,n} e_{n,2} δ^{-1}$ and $r_1 e_{2,n} ↘ r_1 e_{3,n} e_{2,n} e_{3,n} δ^{-1} = e_{2,n} e_{n,2} δ^{-1} = a_{α_2,n} δ^{-1}$ and we are done as $a_{α_2,n} δ^{-1} = a_{α_2,n} δ^{-1} = Z_n$. The other case is similar. Assume, therefore, that these special cases do not occur. If $i = j − 1$, we have $r_i e_{j,n} e_n = r_i β,n e_n$ and we are done. If $i < j − 1$, then $r_i$ commutes homogeneously through to give $e_{j,n} r_i$, unless we have $i = 1$ and $j = 3$, a case that can be treated as $i = 2$ and $j = 3$, which is done below; observe that the expression $e_{j,n} r_i$ is equal to $e_{j,n} s_i = a_{α_j,n} e_{n,2} s_i$ and satisfies all the requirements. If $i = j$, use $r_i e_i$ to see that $r_i e_{j,n} e_n ⇝ e_i e_n ∈ a_{β,n}Z_n$. As above if $i = j + 1$, then by (HNfree), $r_{j+1} e_{j+1} e_{j+2,n} ⇝ r_{j+1} e_{j+1} e_{j+2,n} = r_{j+1} e_{j+1,n} = a_{α_{j+1},n} e_{n,2}$. This is what is required as here $β = α_j$ and $r_{j+1} α_j = α_{j+1}$.

Otherwise, $i > j + 1$ and $r_i e_{j,n} ↘ r_{i-2} r_{i-1} e_{i,n} ≡ e_{j-i-2} r_{i-1} e_{i,n}$. Now if $i < k ≤ 2$, we see $e_{j,i-2} = e_{j,i-3} e_{i-2}$ and we use $e_{i-2} r_{i-1} e_{i-2} r_{i-1} e_{i-2} e_{i,n}$ and, commuting $r_{i-2}$ homogeneously to the right, we obtain the required form.
We may suppose then that $\beta$ has height greater than 1 and so there is a node $j$ for which $\beta - \alpha_j$ is a root. Throughout this part of the proof we use Lemma 5.3 when $\beta - \alpha_j$ is a root to see that up to homogeneous equivalence $a_{\beta,n}e_n \leftrightarrow r_ja_{\beta-\alpha_j,n}e_n$. Again, consider first $e_i a_{\beta,n}e_n$. Choose $j = i$ if possible. If so, we use $e_i r_j \rightarrow e_i$ to obtain $e_i r_j a_{\beta-\alpha_j,n}e_n \rightarrow e_i a_{\beta-\alpha_j,n}e_n$. The resulting word has lower height than $e_i a_{\beta-\alpha_j,n}e_n$ and we use induction to finish. Suppose $i \neq j$ and $i \neq j$. Then $e_i r_j a_{\beta-\alpha_j,n}e_n \rightarrow r_j e_i a_{\beta-\alpha_j,n}e_n$. Now apply the induction hypothesis to $e_i a_{\beta-\alpha_j,n}e_n$, so $e_i a_{\beta-\alpha_j,n}e_n \rightarrow a_{\beta',n}e_{\alpha}$ where $\alpha \in \mathbb{Z}$ and $ht(\beta') < ht(\beta)$. In view of this inequality, induction applies to the statement involving $r_j a_{\beta',n}e_n$. Acting by $r_j$ could raise the height at most one, still leaving $ht(r_j \beta') \leq ht(\beta)$ as needed. Suppose $i \sim j$. We know that $(\alpha_j, \beta)$ is not 1 as we have chosen $j = i$ if possible above. This means either $(\beta, \alpha_i) = 0$ or $(\beta, \alpha_i) = -1$. Suppose first $(\beta, \alpha_i) = 0$. Then $(\beta - \alpha_j, \alpha_i) = 1$ and so $\beta - \alpha_j - \alpha_i$ is a root and $a_{\beta,n}e_n = r_j r_i a_{\beta-\alpha_j-\alpha_i,n}e_n$; now $e_i r_j r_i a_{\beta-\alpha_j-\alpha_i,n}e_n \rightarrow e_i e_j a_{\beta-\alpha_j-\alpha_i,n}e_n$, and we can finish by induction to get the result as the height of the root $\beta - \alpha_j - \alpha_i$ is at most $ht(\beta) - 2$. Suppose now $(\beta, \alpha_i) = -1$. Then $e_i a_{\beta,n}e_n \rightarrow e_i r_j a_{\beta-\alpha_j,n}e_n \rightarrow e_i e_j r_j a_{\beta-\alpha_j,n}e_n$. Notice $(\beta - \alpha_j, \alpha_i) = -1 + 1 = 0$ and so $r_j(\beta - \alpha_j) = \beta - \alpha_j$, from which we derive $e_i a_{\beta,n}e_n \rightarrow e_i e_j r_j a_{\beta-\alpha_j,n}e_n \rightarrow e_i e_j a_{\beta-\alpha_j,n}e_n e_{\alpha}$ for some $\alpha \in \mathbb{Z}$, by the induction hypothesis for the action of $r_i$. Using the induction hypothesis twice more, we find $e_i a_{\beta,n}e_n \rightarrow e_i a_{\beta,n}e_n e_{\alpha} \rightarrow a_{\beta',n}e_{\alpha}$. Here $\beta'$ is a root whose height is at most $ht(\beta) - 1$ and $\beta', \alpha \in \mathbb{Z}$, and we use induction to finish. Therefore, we can assume $(\beta, \alpha_i) = 0$. There is a node $j$ for which $\beta - \alpha_j$ is a root and so $r_j a_{\beta-\alpha_j,n}e_n \rightarrow r_j r_i a_{\beta-\alpha_j,n}e_n$ by Lemma 5.3. The arguments here are similar to the ones at the beginning of this proof when $ht(\beta) > 1$. In particular, if $i \neq j$ and $i \neq j$ this reduces to $r_j r_i a_{\beta-\alpha_j,n}e_n$ and we use induction for $r_i$ acting in the case $(\alpha_j, \beta - \alpha_j) = 0$.

The only remaining case is $i \sim j$ and still $(\beta, \alpha_i) = 0$. Here $\beta - \alpha_i - \alpha_j$ is a root orthogonal to $\alpha_j$ and $a_{\beta,n}e_n \rightarrow r_j r_i a_{\beta-\alpha_j-\alpha_i,n}e_n$ by Lemma 5.3. We consider $r_j r_i a_{\beta-\alpha_j-\alpha_i,n}e_n$ and so use the homogeneous relation $r_j r_i \rightarrow r_j r_i$, the induction hypothesis and $(\alpha_j, \beta - \alpha_j - \alpha_i) = 0$ to derive $r_j r_i a_{\beta-\alpha_j-\alpha_i,n}e_n \rightarrow r_j r_i a_{\beta-\alpha_j-\alpha_i,n}e_{\alpha} \rightarrow a_{\beta',n}e_{\alpha}$ with $\alpha \in \mathbb{Z}$, as required. This proves all but the last part of the lemma.

As for the last statement, without loss of generality, we may assume that $\delta e_n$ is reduced. We argue by induction on the length of $\delta$. Whenever $\delta$ is equal to $a_{\beta,n}$, there is nothing to show. In particular, we may assume that $\delta$ has positive length; say it starts with $e_i$ or $r_i$. By induction, we have $\delta e_n \rightarrow e_i a_{\beta,n}e_{\alpha}$ or $\delta e_n \rightarrow r_j a_{\beta,n}e_{\alpha}$ with $ht(\beta) \leq ht(\delta)$ for some $\alpha \in \mathbb{Z}$. The proof now follows from the second statement in view of $\delta e_n \rightarrow a_{\beta',n}e_{\alpha}$, which is clear from the definition of $a_{\beta',n}$. We now return to the sets $Y \subseteq Y$ and use $Z_Y$ of Notation 6.1 to reduce words of the form $a_{\beta,Y}$. Sometimes we come across $e_n e_n^* e_n$, which is homogeneously equivalent to $e_n e_n e_n^+$ up to powers of $\delta$. In that case, we usually invoke Proposition 6.3.

$\square$
below to reduce the word further. In the other cases, we have $Y = Y(t)$ for some $t$ or $Y = Y'(n/2)$.

**Notation 6.3.** By $\Theta$ we denote the ideal of $\text{Br}(D_n)$ generated by $e_1e_2$. For $U$ any subring of $\text{Br}(D_n)$, we also write $UE_1e_2U$ for the set of all linear combinations of expressions of the form $ue_1e_2v$ with $u, v \in U$. So $\Theta = \text{Br}(D_n)e_1e_2\text{Br}(D_n)$.

Note that $Z_{Y^*(t)}$ is contained in $\Theta$ for each $t \in [1, [n/2]]$.

**Proposition 6.4.** Let $Q$ be the subalgebra of $\text{Br}(D_n)$ generated by all $r_i$ and $e_i$ for $i > 1$. Then $Q$ is isomorphic to $\text{Br}(A_{n-1})$ and satisfies the following properties.

(i) In $F_n$ any word containing $e_1e_2$ can be reduced to a word of the form $ue_1e_2v$ where $u$ and $v$ are words in $r_i$ and $e_i$ for $i > 1$, so $\pi(u), \pi(v) \in Q$.

(ii) The ideal $\Theta$ coincides with $Qe_1e_2Q$. It is isomorphic to the ideal in $Q$ generated by any $e_i$ ($i > 1$). An explicit height preserving isomorphism is determined by $ue_1e_2v \mapsto ue_2v$ for $u, v \in Q$.

**Proof.** The isomorphism of $Q$ with $\text{Br}(A_{n-1})$ follows from the determination of $\text{Br}(D_n)$ in [4].

(i). This can be shown along the lines of the last paragraph of [5, Section 7.1].

(ii). Let $u, v, u', v' \in Q$. By considerations in the Brauer algebra of type $A_{n-1}$ there is a monomial $h$ in the submonoid of $\text{Br}(D_n)$ generated by $e_i, r_i$ for $i \geq 4$, such that $e_2vu'e_2 = e_2h$. We then have

$$ue_1e_2vu'e_2v' = u(e_1e_2v'u'e_2v') = ue_2h(e_1v'v) = u(ue_2h(e_2v)),$$

and the multiplication worked out for $ue_2h(e_2v)$ shows it is equal to $ue_2hv'$, which proves that the indicated map preserves products. The rank of domain and range is

$$\sum_{t=1}^{[n/2]} \binom{n}{2t} \binom{n}{n-2t}^2 (n-2t)!$$

by [4] Lemma 1.3, and so the map is an isomorphism.

As a consequence, the reduction rules for words mapping into $\Theta$ all follow from reductions in $\text{Br}(A_{n-1})$ (applied to elements of the ideal generated by one of the $e_i$). We will be using these observations several times below.

The word $e_{Y(t)}$ commutes homogeneously with the elements $\bar{z}_n$ and $r_i, e_i$ ($i = 1, \ldots, n-2t$), so, up to homogeneous equivalence, it does not matter on which side $e_{Y(t)}$ is located in these expressions for elements of $Z_{Y(t)}$.

**Lemma 6.5.** Fix $t \in \{1, \ldots, [n/2]\}$. Consider a word $a$ for which $aB_{Y(t)}$ is in the same $W$-orbit as $B_{Y(t)}$ and a word $b$ for which $bB_{Y^*(t)}$ is in the same $W$-orbit as $B_{Y^*(t)}$. Then $a\bar{w}_{Y(t)}$ and $b\bar{w}_{Y^*(t)}$ each reduce to a word of the form

$$a_{\beta_{n,n}}a_{\beta_{n-2,n-2t-2}} \cdots a_{\beta_{n-2t+2,n-2t+2}} \bar{z},$$

with $\beta_{n-2k} \in \Phi^+$ for $0 \leq k \leq t-1$ such that $\beta_{n-2k}$ has support in $D_{n-2k}$ for each $k$, and $\bar{z} \in Z_{Y(t)}$ in the first case and $\bar{z} \in Z_{Y^*(t)}$ in the second case. Also, $\beta_n \in \bar{w}_{e_n}(\emptyset)$ and $\{\beta_n, \beta_n^*\} \in \bar{w}_{e_n}(\emptyset)$. The same applies to $Y'(n/2)$ instead of $Y(n/2)$ if $n$ is even.
Proof. Consider first the case of $a$. The statement that $\beta_n \in ae_n(\emptyset)$ is straightforward from the definition and the fact that the terms distinct from $a_{\beta_n,n}$ do not move $a_n = e_n(\emptyset)$.

Notice that $a_{\beta_n,n} a_{\beta_n-2,n-2} \cdots a_{\beta_n-2t+2,n-2t+2} e_Y(t)$ is homogeneously equivalent to $a_{\beta_n,n} e_n a_{\beta_n-2,n-2} e_n a_{\beta_n-2t+2,n-2t+2} e_Y(t-2)$. By Lemma 5.2, $ae_n$ can be reduced to $a_{\beta_n,n} e_n \bar{z}_n$ for some $\beta_n \in \Phi^+$ and $\bar{z}_n \in Z_n$. In particular, up to homogeneuous equivalence, cf. Lemma 5.6(iii), we may assume $\bar{z}_n = a'$ or $\bar{z}_n = a**, a'$ for some $a' \in F_{n-2}$. We denote this as $(a')^\varepsilon a'$ where we set $\varepsilon = 0$ if it is $a'$ and $\varepsilon = 1$ if it is $a** a'$.

If $t = 1$, we are done by Lemma 6.2. Therefore, we may assume $t > 1$. By induction on $n$, we find

$$a'y(t)_{\{\bar{z}_n\}} \leadsto a_{\beta_n,n} a_{\beta_n-2,n-2} e_n a_{\beta_n-2t+2,n-2t+2} e_Y(t-2)$$

for some $\bar{z}_n, e_n, n \in Z_\beta$. If $a \in F_{n-1}$, the terms of $\pi(a' e_Y(t))_{\{\bar{z}_n\}}$ never include $r_n, r_{n-1}, e_n$, or $e_{n-1}$, and so the support of $\beta_{n-1}$ is in $D_{n-1}$.

Now, by Lemma 5.2 for $\varepsilon \in \{0, 1\}$, thanks to $a^{**} e_n a^{**} e_n = e_n a^{**} e_n$, we have, up to powers of $\delta$

$$ae_Y(t) \leadsto a_{\beta_n,n} e_n (\bar{z}_n) a' e_Y(t-2)_{\{\bar{z}_n\}}$$

$$\leadsto a_{\beta_n,n} e_n (\bar{z}_n) a_{\beta_n-2,n-2} e_n a_{\beta_n-2t+2,n-2t+2} e_Y(t-2)$$

$$\leadsto a_{\beta_n,n} e_n a_{\beta_n-2,n-2} e_n a_{\beta_n-2t+2,n-2t+2} e_Y(t-2)$$

$$\leadsto a_{\beta_n,n} e_n a_{\beta_n-2,n-2} e_n a_{\beta_n-2t+2,n-2t+2} e_Y(t-2)$$

with $\bar{z}_n = e_n a_{\beta_n,n} a_{\beta_n-2,n-2} e_n a_{\beta_n-2t+2,n-2t+2} e_Y(t)$ and $\beta_{n-2k}$ has support in $\{\alpha_1, \ldots, \alpha_{n-2k}\}$ for each $k$, as required.

Notice that $a^{**}_n$ homogeneously commutes with elements of $Z_\beta$ by Lemma 5.6 (RSer) and (RSre), and the fact that $a^{**}_n$ starts and ends with $e_n a^{**} e_n$.

The case $ke_Y(t)$ runs along the same lines and is simpler in view of Proposition 5.2.\(\square\)

The special case $t = 1$ gives the following corollary.

Corollary 6.6. If $a(\alpha_n) = \{\beta\}$ or $b(\alpha_n, \alpha^*_n) = \{\beta, \beta^*\}$, then $ae_n \leadsto a_{\beta,n} e_n \bar{z}$ with $\bar{z} \in \bar{Z}$ or $bc_n \leadsto a_{\beta,n} e_n \bar{z}$ with $\bar{z} \in \bar{Z} \{\alpha_n, \alpha^*_n\}$.

Remark 6.7. If $B$ is in the $W$-orbit of $B_\beta$ with $\beta \in B$, then $Ba_{\beta,n} e_n$ is in the same orbit. This is clear for the terms from $W$ in $a_{\beta,n}$ and also for the terms $e_j$ which map $\alpha_{j-1}$ to $\alpha_j$, which is true for $r_j r_{j-1}$. The same is true for $r_j r_{j-1}$ moving $\alpha_1$ to $\alpha_3$.

Now $Ba_{\beta,n} e_n$ contains $\alpha_n$ plus roots all in the subsytem of type $D_{n-2}$. The term $\beta_{n-2}$ is one of these, which can be associated to one of the roots of $B$ other than $\beta$. In this way, an order of the roots of $B$ gives the terms $\beta_{n-2s}$ which occur. The same is true for $Y(t)$ instead of $Y(t)$ if $n$ is even. A similar result is true for the case of $Y^*(t)$; here $Ba_{\beta,n} e_n$ contains $\alpha_n, \alpha^*_n$ as well as roots in $D_{n-2}$ together with their orthogonal mates.

We will consider the different ways to write $ae_Y$ in this reduced form. The case of $t = 2$ will suffice to argue the general case. If $n \geq 5$, there are two possibilities, $Y(2)$ and $Y^*(2)$. As mentioned before, if $n = 4$, there is one more, for $Y = Y^*(2)$.

For $Y = Y(2) = \{n, n-2\}$, we consider words of the form $a_{\beta,n} a_{\beta,n-2,n-2} \bar{z}$ where $\bar{z} \in Z_Y(2)$. We need a lemma that involves words in $F_n$ mapping $\{\alpha_n, \alpha_{n-2}\}$ to
\{\beta, \gamma\} \text{ in } \mathcal{A} \text{ and the ways to reduce them. Similarly for } Y = Y^\ast(2) \text{ we consider words mapping } \{\alpha_n, \alpha_n^\ast, \alpha_n, \alpha_n^\ast\} \text{ to } \{\beta, \gamma\}.\\

**Lemma 6.8.** Suppose that \(a \in F_n\) satisfies \(a(\alpha_n, \alpha_n^\ast) = \{\beta, \gamma\}\) and \(b \in F_n\) satisfies \(b(\alpha_n, \alpha_n^\ast, \alpha_n, \alpha_n^\ast) = \{\beta, \gamma\}\). Then of the two possible reductions of \(ae_2 Y(2)\) and \(be_2 Y(2)\) as in Lemma 6.2, at least one can be reduced to the other, that is, for some \(z \in Z(2)\) or \(z \in Z(2)\), respectively, we have

\[
either a_{\beta, n} a_{\beta, n-2, n-2} \beta, \gamma \rightarrow a_{\gamma, n} a_{\gamma, n-2, n-2} \gamma, \beta \rightarrow a_{\beta, n} a_{\beta, n-2, n-2} \gamma, \beta \rightarrow a_{\gamma, n} a_{\gamma, n-2, n-2} \gamma, \beta
\]

For \(n = 4\) and \(\{\beta, \gamma\} \in W BG(2)\), the same statement holds with \(Y(2)\) instead of \(Y(2)\) and \(\{\alpha_4, \alpha_1\}\) instead of \(\{\alpha_4, \alpha_2\}\).

**Proof:** We deal with \(a\) first. Suppose first that either \(\beta\) or \(\gamma\) has \(n\) in its support. Without loss of generality, we assume \(n \in \text{Supp}(\beta)\). Then \(\pi(a_{\beta, n}) \in W\) as \(n\) is in the support of \(\beta\). By (HNeec),

\[
a_{\beta, n} a_{\beta, n-2, n-2} \rightarrow a_{\beta, n} a_{\beta, n-2, n-2} \gamma, \beta
\]

As \(\pi(a_{\beta, n})\) is in the Weyl group, \(a_{\beta, n} \{\beta_{n-2}\}\) is a single root. As \(a_{\beta, n} a_{\beta, n-2, n-2} \gamma, \beta\) we also have \(\beta_{n-2} \{\alpha_n, \alpha_n^\ast\} = \{\beta, \gamma\}\) we also have \(\{\beta, \gamma\} \in \{\alpha_n, \alpha_n^\ast\}\). Now \(a_{\beta, n} a_{\beta, n-2, n-2} \gamma, \beta\) and \(a_{\beta, n} \{\beta_{n-2}, \alpha_n\} = \{\gamma, \beta\}\). This means \(a_{\beta, n} \{\beta_{n-2}\} = \{\gamma\}\). Also \(a_{\beta, n} a_{\beta, n-2, n} = \{\beta_{n-2}\}\) and so \(a_{\beta, n} a_{\beta, n-2, n} = \{\gamma\}\).

Now Corollary 5.6 and Lemma 5.5 give

\[
a_{\beta, n} a_{\beta, n-2, n} \gamma, \beta \rightarrow a_{\gamma, n} a_{\gamma, n-2, n} \gamma, \beta \rightarrow a_{\gamma, n} a_{\gamma, n-2, n} \gamma, \beta
\]

for some \(z \in Z(2)\) and \(z' \in Z(2)\). In particular the lemma holds in this case.

Suppose then that \(n\) is in the support of neither \(\beta\) nor \(\gamma\). We argue by induction on \(n\). The two reductions of \(ae_2 Y(2)\) are \(a_{\beta, n} a_{\beta, n-2, n-2} \gamma, \beta\) and \(a_{\gamma, n} a_{\gamma, n-2, n-2} \gamma, \beta\) up to right multiples by elements of \(Z(2)\). We know both \(\beta_{n-2}\) and \(\gamma_{n-2}\) do not have \(n\) or \(n-1\) in their support. We will argue that neither has \(n-2\) in the support either. Then \(a_{\beta, n} a_{\beta, n-2, n-2} \gamma, \beta\) and similarly for \(a_{\gamma, n} a_{\gamma, n-2, n-2} \gamma, \beta\).

Notice \(\{\beta, \gamma\} a_{\beta, n-1} = \{\gamma', \alpha_{n-1}\}\) and \(\{\beta, \gamma\} a_{\beta, n-1} = \{\beta_{n-2}, \alpha_n\}\). Now \(\gamma'\) is a root lying in the subsystem of type \(\gamma' \in D_{n-1}\) and so does not have \(n\) in its support. Moreover, \(\{\alpha_n-1, \gamma'\} = 0\) and \(\gamma' \neq \alpha_{n-1}^\ast\) as \(\{\beta, \gamma\}\) is in the \(W\)-orbit of \(B(2)\). This means \(\gamma'\) does not have \(n-2\) in its support either or \(\{\gamma', \alpha_{n-2}\} = -1\), in which case, by definition, \(\gamma' = \beta_{n-2}\) and this root does not have \(n-2\) in its support as claimed.

The two reductions of \(ae_2 Y(2)\) are now \(a_{\beta, n-1} a_{\beta, n-2, n} \gamma, \beta\) and \(a_{\gamma, n-1} a_{\gamma, n-2, n} \gamma, \beta\) up to right multiples by elements of \(Z(2)\).

Now both \(a_{\beta, n-1} a_{\beta, n-2, n} \gamma, \beta\) and \(a_{\gamma, n-1} a_{\gamma, n-2, n} \gamma, \beta\) belong to \(F_{n-1}\). By induction on \(n\), one can be reduced to the other—up to a right factor from \(Z(\{\alpha_n, n-1, n-2\})\), say

\[
a_{\beta, n-1} a_{\beta, n-2, n} \gamma, \beta \rightarrow a_{\gamma, n-1} a_{\gamma, n-2, n} \gamma, \beta
\]
for $z' \in Z_{(\alpha_{n-1}, \alpha_n^-)}$. Due to (HNece) and the definition of $Z_{n-1}$ we have $z_{n-1}^{*} e_{n-2} \approx e_{n-1} z_{n-2}^{*}$. Terms in $z'$ generated by $e_i$ or $r_i$ with $i < n - 3$ are in $Z_{Y(2)}$. If there is $z_{n-3}^{*}$, then, using Lemma [5.6]iv), we can replace it with $z_{n-1}^{*}$. If $z'$ is a product of generators with index less than $n - 4$ we have $z'e_{n} e_{n-2} \approx e_{n-1} z_{n-2}$ with $z' \in Z_{Y(2)}$. In case $z' = z_{n-1}^{*}$, we find $z_{n-1}^{*} e_{n} e_{n-2} \approx z_{n-1}^{*} e_{n-2} e_{n} \approx e_{n-1} z_{n-2}^{*} e_{n-2} e_{n} \delta^{-1} \approx e_{n-1} e_{n} e_{n-2} e_{n} \delta^{-1} z_{n-2}^{*}$, as $e_{n-2} \approx e_{n-2} \delta^{-1}$.

Now multiplication by $e_{n} e_{n-2}$ on both sides of the reduction (2) and application of Lemma [5.6]iv) gives

$$a_{\gamma,n} e_{n} a_{\gamma,n-2} e_{n-2} \approx a_{\gamma,n} e_{n} a_{\gamma,n-2} e_{n-3} z_{n}^{*} e_{n-2} e_{n} \approx a_{\gamma,n} e_{n} a_{\gamma,n-2} e_{n-3} e_{n} z_{n}^{*} \approx a_{\gamma,n} e_{n} a_{\gamma,n-2} e_{n-2} e_{n}$$

for $z \in Z_{n}$, as required. Here, $z$ is the same as $z'$ unless $z'$ has a factor $z_{n-1}^{*}$ or $z_{n-3}^{*}$, in which case we can take it to be $z_{n-1}^{*}$ by Lemma [5.6]. In the case with $z_{n-1}^{*}$ occurring, the extra $e_{n-1}$ commutes to the left. If $z' = z'' z_{n-1}^{*}$, then $z$ reduces to $z'' z_{n-1}^{*}$.

Next we deal with $b$. In this case again, using Proposition [6.4], we can proceed as above. The words $b_{e_{Y}, (2)}$ can be taken to belong to the subalgebra $Q$ of type $A_{n-1}$ and so the reduction is simpler. Notice here \{$\beta, \beta^*, \gamma, \gamma^*$\} $a_{\beta,n} e_{n} = \{\gamma', \gamma'^*, \alpha_{n}, \alpha_{n}^*\}$ with support of $\gamma'$ in $D_{n-2}$.

This case, for just two roots, extends to admissible sets of arbitrary size by the next lemma.

**Lemma 6.9.** Let $a$ be a word in $F_2$ and choose $Y \in \mathcal{Y}$ such that $a(\emptyset) \in W_{e_{Y}}$. Let $t \in \{0, \ldots, \lfloor n/2 \rfloor \}$ be such that $Y \in \{Y(t), Y'(t), Y^*(t)\}$. Then there are positive roots $\beta_{n-2k}$ for $k = 0, \ldots, t - 1$ such that $\beta_{n-2k}$ has support in $D_{n-2k}$ for each $k$ and $a_{e_{Y}}$ can be reduced to an element of $a_{e_{Y}} Z_{Y}$ where

$$a' = a_{\beta,n} a_{\beta,n-2} \ldots a_{\beta,n-2t+2}$$

and every word reduced from $a_{e_{Y}}$ as in Lemma [6.5] can also be reduced to a word in $a' Z_{Y}$.

**Proof.** Set $B = a_{e_{Y}}$. By Lemma [6.5] there is a unique reduction up to right multiplication by elements of $Z_{Y}$ for each ordering of the elements of $B$. We use Lemma [6.8] to see that the order of, say the first two, does not matter, in the sense that one reduction can be reduced to another. Continuing this way with $\alpha_{n-2}$ and $\alpha_{n-4}$, we see that the words as in Lemma [6.5] for all orders of the roots of $B$ can be reduced to a particular one. This proves the lemma.

**Notation 6.10.** The lemma allows us to define $a_{B,n}$, for $B \in W_{e_{Y}}$, as the unique word $a'_{e_{Y}} \in F_n$ up to homogeneous equivalence and powers of $\delta$ determined by Lemma [6.9] with $B = a'_{e_{Y}} = a'_{e_{Y}}(\emptyset)$. When $t = 0$, we take $a_{B,n}$ to be the identity of the Brauer algebra.

The sets $U_{Y}$ were introduced in Proposition [5.3] iii).

**Theorem 6.11.** Each $a \in F_n$ can be reduced to a word of the form $a_{B,n} z_{B'} \delta^{k}$ where $k$ is an integer, $B, B' \in W_{e_{Y}}$, and $z \in U_{Y}$ for some $Y \in \mathcal{Y}$. 

Proof. Put $B = a(\emptyset)$ and $B' = a^{op}(\emptyset)$. It follows from Lemma 6.5 that the two sets belong to the same $W$-orbit inside $A$, namely the one containing $B_Y$. It suffices to prove the statement of the theorem for $Z_Y$ instead of $U_Y$ because $a(\emptyset) = B$ and, by Proposition 4.5, the presence of $e_Y e_i$ in $z$ for some $i$ non-adjacent to all members of $Y$ in $M$ would imply that $a_{B,n} z a_{B',n}^{op}(\emptyset)$ contains $a_{B,n}(B_Y \cup \{\alpha_i\})$, a set of size greater than $|B|$; however $a(\emptyset) = B$ has size $|B|$, a contradiction.

Consider the case $Y = Y(t)$ and suppose $B \in WB_Y(t)$. If $B = \emptyset$, then $a_{B,n}$ does not contain any occurrences of $e_i$ for $e_i(\emptyset)$ contains $\alpha_i$ (cf. the last assertion of Proposition 4.5). This means that $a_{B,n}$ is a product of $r_i$ and the Matsumoto–Tits rewrite rules for $W$ suffice for the validity of the theorem in this case, with $t = 0$ and $Y = Y(0) = \emptyset$.

Therefore, we may assume that $B \neq \emptyset$, so there is an index $i$ such that $e_i$ occurs in $a_{B,n}$. If $i \neq n$, then by homogeneous equivalence, we can replace $e_i$ by $e_{i,n} e_{n-1,i}$. Thus $a = b_{i,n} c$ for certain $b, c \in F_n$. By Lemma 6.5 applied both to $b$ and $a^{op}$, we can reduce $a$ to $a_{\beta,n} a_{\beta,n}^{op}$ for some $\beta \in B$, $\beta' \in B'$ and $a_{B,n} = a_{\beta,n}$ in $\mathbb{Z}$. Then, by an argument as in the proof of Lemma 6.5, $a_{B,n} = e_n a_{\beta,n}(z^\ast) e_n^{-1}$ with $\beta' \in F_n$ and $\varepsilon \in \{0,1\}$. This deals with the case where $t = 1$.

Suppose $t > 1$. By induction on $n$, the word $a'$ reduces to $a_{D,n-2} z'^{op}_{D,n-2}$ for some $z' \in Z_{X'}$, where $X'' = \{\alpha_{n-2}, \ldots, \alpha_{n-2|t+2|}\}$ and $D$ and $D'$ are admissible sets in the root system of type $D_{n-2}$ with support in $\{1, \ldots, n-2\}$. Due to Lemma 5.3, if $\varepsilon = 1$:

$$e_n e_{n-2} z^{\ast}_{n-2} \leftrightarrow e_n e_{n-2} z^{\ast}_{n-2} \leftrightarrow e_n e_{n-2} z^{\ast}_{n-2} \leftrightarrow e_n e_{n-2} z^{\ast}_{n-2}.$$ 

By induction on $t$, this gives $e_{Y(t)} Z_{X'} \leftrightarrow e_{Y(t)} Z_{X'} \leftrightarrow e_{Y(t)} Z_{X'}$, which is the same as $e_{n} e_{X'} z^\ast_{n} \leftrightarrow e_{n} e_{X'} z^\ast_{n-2t+2}$. So, by Lemmas 6.9 and 5.6 parts (ii) and (iv),

$$a \leftrightarrow e_{n} e_{X'} z^\ast_{n} \leftrightarrow e_{n} e_{X'} z^\ast_{n-2t+2} \leftrightarrow e_{n} e_{X'} z^\ast_{n-2t+2}.$$ 

for some $z \in Z_{Y(t)}$. This handles the case $Y = Y(t)$.

If $B \in WB_Y(t)$, the same arguments apply. Finally, if $B \in WB_Y(t)$, then, due to Proposition 6.4, the same arguments apply to $Q$ with the root system of type $A_{n-1}$ having support in $\{2, \ldots, n\}$.

The following corollary extends Lemma 5.5 to the Brauer monoid.

Corollary 6.12. For each $a \in F_n$, all reduced elements of $F_n$ reducible from $a$ are homogeneously equivalent to an element of the form $a_{B,n} z a_{B',n}^{op} \delta_k$ with $B$ and $B'$ in $WB_Y$ for some $Y \in \mathcal{Y}$ and $\varepsilon \in U_Y$. Here the elements $B$ and $B'$ are uniquely determined by $B = a(\emptyset)$ and $B' = a^{op}(\emptyset)$, respectively.

Proof. The form is immediate from the theorem. Uniqueness up to homogeneous equivalence follows from Lemma 6.9 for $a_{B,n}$ and $a_{B',n}$ and from the Matsumoto–Tits' rewrite rules for $\varepsilon \in U_Y$, as stated in Proposition 5.8. 

As a consequence of Corollary 6.12, all reduced words that are reductions from $a \in F_n$ in $Br(D_n)$ are homogeneously equivalent.

The proof of Corollary 6.12 has implications for the ordinary Brauer algebra of type $A_{n-1}$ which we can take to be generated by $r_i$, $e_i$ for $2 \leq i \leq n$. Here there are no
$r_i^*$, and $U_{Y(t)}$ consists of the reduced words on $t^i$ for $2 \leq i \leq n - 2t$, while $W$ is generated by the $r_i$ for $2 \leq i \leq n$ and is isomorphic to the symmetric group of $n$ points.

**Corollary 6.13.** Let $Br(A_{n-1})$ be the Brauer algebra of type $A_{n-1}$. Let $\pi$ be the map from $F_{n-1}$ to $Br(A_{n-1})$ taking $r_i$ or $e_i$ to the element in $Br(A_{n-1})$ with the same label. For each $a \in F_{n-1}$, all reduced words in $F_n$ reducible from $a$ are homogeneously equivalent to an element of the form $a_{B,n-1}a_{B,n-1}^\delta B$ and $B'$ in $WB_{Y(t)}$ for some $t \in \{0, 1, \ldots, \lfloor \frac{n-1}{2} \rfloor \}$ and $z \in U_{Y(t)}$. Here the elements $B$ and $B'$ are uniquely determined by $B = a(\emptyset)$ and $B' = a(\emptyset)$, respectively. Also, $U_{Y(t)}$ is the Weyl group of type $A_{n-1-2t}$.

We chose the index $n-1$ here so there will be no confusion between these coefficients and the ones in Corollary 6.12.

### 7. Proof of Theorem 1.1 and Corollary 1.3

In this section we prove Theorem 1.1 and Corollary 1.3.

**Proof of Theorem 1.1.** By Lemma 3.8, the rank of $B(D_n)$ is at least $\dim(\text{Br}(D_n))$, which by [4, Theorem 1.1] equals $(2^n + 1)n! - (2^{n-1} + 1)n!$.

Now let $T$ be the set of elements $a_{B,n}a_{B,n}^\delta$ in $F_n$ as in Corollary 6.12. Then the elements of $T$ correspond to triples $(B, B', z)$, where $B$ and $B'$ are in the $W$-orbit in $\mathcal{A}$ containing $B_Y$ for some $Y \in \mathcal{Y}$ and $z \in U_Y$. Now $T$ is a finite set and, by Corollary 6.12, every $a \in F_n$ reduces to an element of $T$ up to a power of $\delta$.

For the remainder of the proof of the first statement of Theorem 1.1, we note that, by [4, Proposition 4.9 and the proof of Theorem 1.1], $(\pi(t))_{t \in T}$ is a basis of $\text{Br}(D_n)$. Now Proposition 5.9 applies, so $(\rho(t))_{t \in T}$ is a basis of $B(D_n)$. This shows that $B(D_n)$ is free of rank as claimed in Theorem 1.1.

To show that $B(D_n)$ tensored over $\mathbb{Q}(l, \delta)$ is semisimple we use the surjective equivariant map $\mu : B(D_n) \otimes R \mathbb{Q}(\delta)[l^{\pm 1}] \to \text{Br}(D_n)$ over $\mathbb{Q}(\delta)$; cf. Definitions 5.3. We know its image $\text{Br}(D_n)$ is semisimple by [4, Corollary 5.6] and so has no nilpotent left ideals. Suppose $\text{Br}(D_n) \otimes R \mathbb{Q}(\delta, l)$ has a nontrivial nilpotent ideal. Take a nonzero element of it expressed in the basis we have found. Multiply the element by a suitable polynomial in $l$ so that all coefficients are in $\mathbb{Q}(\delta)[l^{\pm 1}]$. As in the proof of Lemma 5.8 rescale the coefficients by a power of $l - 1$ so that all coefficients remain in $\mathbb{Q}(\delta)[l^{\pm 1}]$ but some coefficient $\lambda$ lies outside $(l - 1)\mathbb{Q}(\delta)[l^{\pm 1}]$. The result is a nonzero nilpotent element in $B(D_n) \otimes \mathbb{Q}(\delta)[l^{\pm 1}]$ with $\mu(\lambda) \neq 0$, so its image under $\pi$ is a nonzero nilpotent element of $\text{Br}(D_n)$. Furthermore, any multiple is nilpotent both in $B(D_n) \otimes \mathbb{Q}(\delta, l)$ and in $\text{Br}(D_n)$ and so generates a nontrivial nilpotent ideal of $\text{Br}(D_n)$, a contradiction. This completes the proof of Theorem 1.1.

Although we did not need the statement for the proof of the main theorem, it may be worthy of mention that, by Proposition 5.9, each word in $T$ as above is reduced.

We will need the elements $\rho(a_{B,n})$ for the words $a_{B,n}$ in $F_n$ introduced in Notation 6.10. These words were defined up to homogeneous equivalence. Since different elements from the homogeneous class of $a_{B,n}$ may give different elements in $B(D_n)$, see Remark 5.4, we need to select a particular element in each class.

**Notation 7.1.** Let $Y \in \mathcal{Y}$. For each $B \in WB_Y$, we take $a_{B,n}$ to be a specific word in $F_n$ from its homogeneous equivalence class in $F_n$ and write $b_{B,n} = \rho(a_{B,n})$ for its image in $B(D_n)$ under $\rho$. 

---

The document contains a proof of a theorem in algebra, focusing on the Brauer algebra and its properties. The proof involves using surjective maps and tensors over certain fields to establish the semisimplicity of $B(D_n)$. It also highlights the need to select particular elements from homogeneous classes for different elements in $B(D_n)$.
Corollary 7.2. For \( n \geq 4 \), the elements \( b_{B,n} \rho(\xi) b_{B',n} \) for \((B, B', \xi) \in \bigcup_{Y \in \mathcal{Y}} WB_Y \times WB_Y \times U_Y \) are a basis of \( B(D_n) \).

Remark 7.3. Let \( \Theta' \) be the ideal of \( B(D_n) \) generated by \( e_1 e_2 \). We can also choose a basis of \( \Theta' \) of the form \( b_{B,n-1} \rho(\xi) b_{B',n-1} \) where the \( b_{B,n-1} \) are chosen as in Notation 7.1 using Corollary 6.13 for \( Br(A_{n-1}) \).

Remark 7.4. A consequence of Theorem 1.1 is that natural subalgebras generated by \( \{g_i, e_i \mid i \in K\} \) for \( K \) a set of nodes of \( M \) have the usual desired subalgebra structure, that is, are naturally isomorphic to the BMW algebra whose type is the restriction of \( M \) to \( K \). In particular, the subalgebra generated by \( \{g_i, e_i \mid 2 \leq i \leq n\} \) is the full \( B(A_{n-1}) \) rather than a proper homomorphic image. The same applies to the algebra generated by all \( g_i, e_i \) for \( i \leq n - 1 \) which is \( B(D_{n-1}) \) and not a proper image.

Proof of Corollary 1.3. The generalized Temperley–Lieb algebra of type \( D_n \) has been studied in [11, 15, 18]. The elements \( e_i \) either in \( B(D_n) \) or in \( Br(D_n) \) commute for \( i \not\sim j \) by (HCee). For \( i \sim j \), we have \( e_i e_j e_i = e_i \) by (HNeee). Also, \( e_i^2 = \delta e_i \) by (HSee). The free algebra on \( e_1, \ldots, e_n \) with this presentation over \( \mathbb{Z}[\delta \pm 1] \) is called the (generalized) Temperley–Lieb algebra of type \( D_n \) over \( \mathbb{Z}[\delta \pm 1] \); we will denote it by \( TL(D_n) \). The subalgebra generated by \( e_1, \ldots, e_n \) in \( Br(D_n) \) is a homomorphic image of \( TL(D_n) \); the subalgebra of \( B(D_n) \) generated by these elements is a homomorphic image of \( TL(D_n) \otimes \mathbb{Z}[\delta \pm 1] \). The words in \( F_n \) corresponding to generators for these subalgebras consist solely of the symbols \( e_1, \ldots, e_n, \delta \) and so are of height 0. In [18], Theorem 4.2 and Lemma 6.5, a description of a generating set for the Temperley–Lieb algebra is given in terms of decorated diagrams with some restrictions. In [7], diagrams such as these were introduced for the full algebra \( Br(D_n) \). In particular, in [7, Theorem 1.1] it is shown there is an isomorphism, \( \nu \), from \( Br(D_n) \) to the span of the diagrams as a basis over \( \mathbb{Z}[\delta, \delta^{-1}] \). In [18], Lemmas 6.5 and 6.6, it is shown that the specific images \( \nu(e_i) \) generate the full Temperley–Lieb algebra and so the \( e_i \) in \( Br_n(D_n) \) generate the full Temperley–Lieb algebra. The actual multiplication of \( \nu(e_i) \) with \( \nu(e_j) \) in [7, Section 4] has a coefficient \( \xi \) which sometimes appears. However, by results in [7] the coefficient \( \xi \) does not appear for words of height 0 and so does not appear here.

Now apply Proposition 6.13 to see that the algebra generated by \( \rho(e_i) \) is the full Temperley–Lieb algebra over \( R \).

This completes the proof of Corollary 1.3. It follows from this that the subalgebra of \( Br(D_n) \) generated by \( e_j \) (\( j \geq 2 \)) is isomorphic to the Temperley–Lieb algebra of type \( A_{n-1} \).

In [8], it is shown that the Temperley–Lieb monomials are the terms \( a_{B,n} \) for \( B \) of height 0, where the concept of height 0 for \( B \) is given in Section 9.

Remark 7.5. By use of \( \mu \) and the Tits Deformation Theorem, see [3, IV.2, exercise 26] or [25, Lemma 85], it can be shown that the irreducible degrees associated to \( B(D_n) \) are the same as for \( Br(D_n) \). This can also be shown by use of Theorem 6.11 for representations with \( \Theta' \) in the kernel as in [4] and for the others from the connection of \( \Theta' \) to \( B(A_{n-1}) \) as in the proof of Theorem 1.1.
8. Cellularity

Let $S$ be a commutative algebra over $R$. In this section we prove Theorem 1.2 which states that $B(D_n) \otimes_R S$ is cellular in the sense of Graham–Lehrer [16, Definition 1.1] if $S$ contains an inverse to 2. We recall the definition from [16].

**Definition 8.1.** An associative algebra $A$ over a commutative ring $S$ is **cellular** if there is a quadruple $(\Lambda, T, C, \ast)$ satisfying the following three conditions.

1. $(i)$ $A$ is a finite partially ordered set. Associated to each $\lambda \in \Lambda$, there is a finite set $T(\lambda)$. Also, $C$ is an injective map
   
   \[ C : \prod_{\lambda \in \Lambda} T(\lambda) \times T(\lambda) \to A \]

   whose image is an $S$-basis of $A$.

2. $(ii)$ The map $\ast : A \to A$ is an $S$-linear anti-involution such that $C(x, y)^\ast = C(y, x)$ whenever $x, y \in T(\lambda)$ for some $\lambda \in \Lambda$.

3. $(iii)$ If $\lambda, \mu, \nu, \gamma \in \Lambda$ and $x, y \in T(\lambda)$, then, for any element $a \in A$,
   
   \[ aC(x, y) = \sum_{u \in T(\lambda)} r_a(u, x)C(u, y) \mod A_{\leq \lambda}, \]

   where $r_a(u, x) \in S$ is independent of $y$ and where $A_{\leq \lambda}$ is the $S$-submodule of $A$ spanned by $\{C(x', y') \mid x', y' \in T(\mu)\}$ for $\mu \leq \lambda$.

Such a quadruple $(\Lambda, T, C, \ast)$ is called a **cell datum** for $A$.

Now let $S$ be an integral domain containing $R$ as a subring with $2^{-1} \in S$. We introduce a quadruple $(\Lambda, T, C, \ast)$ and prove that it is a cell datum for $A = B(D_n) \otimes_R S$. The map $\ast$ on $A$ will be the opposition map $\ast_{op}$ of Notation 3.6. Before describing the other three components of the quadruple $(\Lambda, T, C, \ast)$, we will relate the subalgebras of $A$ generated by monomials corresponding to the elements of $U_Y$, defined in Proposition 5.8(iii), to Hecke algebras. For this purpose we need a version of Proposition 5.8 that applies to $A$ rather than $B(D_n)$. This requires a version of Lemma 5.6 for $B(D_n)$ rather than $F_\mu / \sim$, with $\sim$ replaced by equality in $B(D_n)$. Here, as in Remark 7.3, we let $\Theta^\prime$ be the ideal of $B(D_n)$ generated by $e_1e_2$.

**Lemma 8.2.** For $n \geq 3$, the monomials $\hat{z}_n^\ast = \rho(z_n^\ast)$ in $B(D_n)$ satisfy the following equations, where $g_n^\ast = \rho(g_n^\ast)$. Here we are considering $e_i$ and $g_i$ to be in $B(D_n)$, namely $g_i = \rho(r_i)$ and $e_i = \rho(e_i)$ where $r_i \in F_n$ and the $e_i$ within the parentheses is also in $F_n$.

1. $(i)$ $g_n^\ast e_n = \hat{z}_n^\ast = e_n g_n^\ast$.
2. $(ii)$ $\hat{z}_n^\ast = e_n g_2 e_1 e_3 \cdots n$.
3. $(iii)$ For $n \geq 4$ and $i \in \{1, \ldots, n-2\}$, $e_i \hat{z}_n^\ast = \hat{z}_i^\ast e_n = e_n \hat{z}_n^\ast$ and $g_i \hat{z}_n^\ast = \hat{z}_n^\ast g_i$.
4. $(iv)$ $\hat{z}_n^\ast e_{n-2} = e_n \hat{z}_{n-2}^\ast$ and $e_n \hat{z}_n^\ast = \hat{z}_n^\ast e_n = \delta \hat{z}_n$.
5. $(v)$ $\left(\hat{z}_n^\ast\right)^2 \in \delta e_n - m \delta \hat{z}_n^\ast + \Theta^\prime$.

For $n$ equal to 1 or 2, both $(i)$ and $(v)$ hold.

**Proof.** Many of the proofs are the same as for Lemma 5.6. Differences occur when the relations are not monomial as extra terms occur with coefficients divisible by $m$.

(i). The proof is similar to the one of Lemma 5.6(ii); note that the relations (RNre) for $B(D_n)$ are also binomial.
Proposition 8.4. Again, the only relation used in the proof of Lemma 5.6(ii) is \((\text{HTeer})\), which is binomial for \(B(D_n)\).

(iii). Let \(i \in \{2, \ldots, n - 2\}\). The relation \(e_i \hat{z}_n^* = e_n \hat{z}_i^*\) can be derived from the definition of \(e_k\), and the binomial relations \((\text{HCee})\) and \((\text{HNeee})\), as in the proof of Lemma 5.6.

The proof of \(g_i \hat{z}_n^* = \hat{z}_n^* g_i\) is a bit more involved. By \((\text{HCer})\), \((\text{RNrr})\), \((\text{RSrr})\) and \((\text{RNerr})\),

\[
g_i \hat{z}_n^* = e_{n,i+2} e_i e_{i+1,2} e_i e_{3,2} e_3 e_3 = e_{n,i+2} e_i e_{i+1,2} e_i e_{3,2} e_3 e_3, n
\]

\[
+ m l^{-1} e_{n,i+2} e_i e_{i+1,2} e_i e_{3,2} e_3 e_3, n
\]

\[
= e_{n,i+2} e_i e_{i+1,2} e_i e_{3,2} e_3 e_3, n - m e_n e_i e_{i+1,2} e_i e_{3,2} e_3 e_3, n
\]

\[
= e_{n,i+1} e_i e_{i+1,2} e_i e_{3,2} e_3 e_3, n - m \hat{z}_n^* + m e_i e_{i+1,2} e_i e_{3,2} e_3 e_3, n
\]

\[
= e_{n,2} e_i e_{i+1,2} e_i e_{3,2} e_3 e_3, n - \hat{z}_n^* + m \hat{z}_i e_n
\]

Since each of the three summands is invariant under opposition, (observe that \((\hat{z}_n^*)^\text{op} = \hat{z}_n^*\) follows from (i)), so is \(g_i \hat{z}_n^*\). This shows \(g_i \hat{z}_n^* = (g_i \hat{z}_n^*)^\text{op} = (\hat{z}_n^*)^\text{op} g_i = \hat{z}_n^* g_i\).

The case \(i = 1\) is notationally different but can be done the same way as \(i = 2\).

(iv). By (iii) with \(i = n - 2\) we have \(e_{n-2} \hat{z}_n^* = \hat{z}_n^* - e_n \hat{z}_{n-2}^*\). Taking images under \(^\text{op}\) and using opposition invariance of \(\hat{z}_n^*\), we find \((\hat{z}_n^*)^\text{op} = (e_{n-2} \hat{z}_n^*)^\text{op} = e_n \hat{z}_{n-2}^*\), as required for the first equation. The second chain of equations is a direct consequence of \((\text{RSee})\).

(v). For \(n \geq 3\), by \((\text{HSee})\), \((\text{HCer})\), \((\text{HNee})\), and \((\text{RRrr})\),

\[
(\hat{z}_n^*)^2 = e_{n,3} e_3 e_3 e_3, n = e_{n,3} e_3 e_3 e_3, n \delta
\]

\[
= \delta e_{n,3} e_3 e_3 e_3, n - \delta e_{n,3} e_3 e_3 e_3, n = \delta e_{n,3} e_3 e_3, n
\]

\[
= \delta e_{n,3}(1 - m g_1 + m l^{-1} e_1 e_2, n
\]

\[
= \delta e_{n,3} e_2, n - \delta m e_{n,3} e_1 e_2, n + \delta m l^{-1} e_{n,3} e_1 e_2, n
\]

\[
\in \delta e_{n,3} e_2, n - \delta m e_{n,3} e_1 e_2, n + \delta m l^{-1} e_{n,3} e_1 e_2, n
\]

The cases \(n = 1\) and \(n = 2\) are easily proved.

\begin{definition}
For \(t \in \{0, \ldots, \lfloor n/2 \rfloor\}\), we write \(J_{t+1}\) to denote the ideal of \(A_{\text{op}}\) generated by \(\Theta'\), \(e_{Y(t)}\) for all \(t' > t\), and \(e_{Y'(n/2)}\) if \(n\) is even and \(n > 2t\). In particular, \(J_1\) is the ideal generated by all \(e_i\) and, for \(n\) even with \(t = n/2\), the ideal \(J_{t+1}\) coincides with \(\Theta'\).

Recall the words \(s_i\) \((0 \leq i \leq n - 2t)\) and \(\hat{e}_{Y(t)} = e_{Y(t)} \delta^{-t}\) given in Notation 5.7

\begin{proposition}
Let \(t \in \{0, \ldots, \lfloor n/2 \rfloor\}\). The monomials \(\tilde{s}_i = \rho(s_i)\), for \(i\) a node of \(M_{Y(t)}\), satisfy the following relations.

(i) The element \(\rho(\hat{e}_{Y(t)})\) acts as an identity element on the \(\tilde{s}_i\), that is, \(\rho(\hat{e}_{Y(t)}) \tilde{s}_i = \tilde{s}_i\) and \(\rho(\hat{e}_{Y(t)}) \tilde{s}_i = \tilde{s}_i\), while \(\rho(\hat{e}_{Y(t)})^2 = \rho(\hat{e}_{Y(t)})\). Moreover, the \(\tilde{s}_i\) satisfy the braid relations \((\text{HCrr})\) and \((\text{HNrr})\) of Table I with \(g_i\) replaced by \(\tilde{s}_i\) and \(1\) by \(\rho(\hat{e}_{Y(t)})\).
\end{proposition}
Corollary 8.6. Each monomial $s_i$ satisfies the quadratic Hecke algebra relation modulo the ideal $J_{t+1}$, that is, $s_i^2 + ms_i - \rho(e_Y(t)) \in J_{t+1}$.

If $n$ is even and $t = n/2$, the corresponding statement holds for $Y'(n/2)$ replacing $Y(n/2)$.

Proof. Here again $g_i$ and $e_i$ are considered in $B(D_n)$.

(i). The relations involving $\rho(\hat{e}_Y(t))$ are easily derived from Lemma 8.5. Note the resemblance with the proof of Proposition 5.8. Use of (RSrr), (HCrr), and (HNrr) gives the relations not involving $\hat{s}_0$. It remains to verify the commuting of $\hat{s}_0$ with $\hat{s}_i$ for $i \in \{1, \ldots, n-2t\}$. By Lemma 8.5(iii) $g_i \hat{e}_n^* = \hat{s}_i$. This gives

$$\hat{s}_0 \hat{s}_i = \hat{s}_0 \hat{s}_i = \hat{s}_0 \hat{s}_i \hat{e}_Y(t)g_i \hat{e}_Y(t) = \hat{s}_0 \hat{s}_i \hat{e}_Y(t) = \hat{s}_i \hat{s}_0.$$

(ii). For $i \in \{1, \ldots, n-2t\}$, we have $s_i^2 = g_i \hat{e}_Y(t)g_i \hat{e}_Y(t) = g_i \hat{e}_Y(t) = (1 - mg_i + ml^{-1}e_i) \hat{e}_Y(t) = \hat{e}_Y(t) - ms_i + ml^{-1}e_Y(t)\delta^{-1-t}$. Here $e_Y(t)_{J_{t+1}}$ is in $J_{t+1}$, so $s_i^2 + ms_i - \hat{e}_Y(t) \in J_{t+1}$.

As for $\hat{s}_0^2$, by Lemma 8.5(iv), $\hat{e}_n^* e_Y(t) = e_Y(t) \hat{s}_n^* - 2t + 2$ and $e_Y(t) \hat{s}_n^* = \hat{s}_n^* - 2t + 2 e_Y(t)$, so, by Lemma 8.5(iii), (iv), (v), and in view of $\Theta' \subseteq J_{t+1}$, we have

$$\hat{s}_0^2 = \hat{s}_0^2 e_Y(t) \hat{s}_n^* e_Y(t) \delta^{-2t+2} = \hat{s}_0^2 e_Y(t) \hat{s}_n^* e_Y(t) \delta^{-2t+2}$$

$$\in e_Y(t)(\hat{s}_n^* - 2t + 2) e_Y(t) \delta^{-2t+1} + J_{t+1}$$

$$\rho(\hat{e}_Y(t)) - m \hat{s}_n^* e_Y(t) e_Y(t) \delta^{-2t+1} + J_{t+1}$$

$$\rho(\hat{e}_Y(t)) - m \hat{s}_n^* e_Y(t) \delta^{-t+1} + J_{t+1}$$

$$\rho(\hat{e}_Y(t)) - m \hat{s}_0 + J_{t+1}.$$

We will next exploit the elements $b_{B,n}$ of Notation 8.1. Recall from Proposition 5.8(iii) the definition of $U_Y(t)$.

Notation 8.5. Let $H_Y$ be the linear span of $\rho(U_Y)$.

Corollary 8.6. For $t \in \{0, \ldots, \lfloor n/2 \rfloor\}$, the linear subspace $H_Y(t)$ of $A$ satisfies the following properties.

(i) The linear subspace $H_Y(t) + J_{t+1}$ is a subalgebra of $A$ whose quotient algebra mod $J_{t+1}$ is isomorphic to the Hecke algebra of type $M_Y(t)$. Moreover, $\rho(U_Y(t))$ is a basis of $H_Y(t)$.

(ii) For each $i \in \{1, \ldots, n\}$ and $B \in WY(t)$, we have $g_i b_{B,n} e_Y(t) \in b_{r_i, B,n} H_Y(t) + J_{t+1}$ and $e_i b_{B,n} e_Y(t) \in b_{r_i, B,n} H_Y(t) + J_{t+1}$ for some $B'' \in WY(t)$.

(iii) The linear subspace $H_Y(t)$ is invariant under opposition.

If $n$ is even, the similarly defined linear span $H_Y'(n/2)$ equals $S \hat{e}_Y'(n/2)$ and satisfies the same properties.
Proof. If \( a \in U_{Y(t)} \) is a minimal expression in the \( s_i \) of the element \( \pi(a) \in W(M_{Y(t)}) \), then, as a consequence of Lemma 5.3 and the relations established in Proposition 8.4(ii), \( \rho(a) \) depends only on \( \pi(a) \) and not on the choice of the minimal expression.

(i). By the above and Proposition 8.4(ii), the spanning set \( \rho(U_{Y(t)}) \) of \( H_{Y(t)} \) has size at most \(|W(M_{Y(t)})|\). Due to Corollary 7.2 there is no collapse, so the spanning set has size equal to \(|W(M_{Y(t)})|\) and is a basis of \( H_{Y(t)} \). By Proposition 8.4 the linear subspace \( H_{Y(t)} + J_{t+1} \) is closed under multiplication and satisfies the Hecke algebra defining relations mod \( J_{t+1} \) on the generators \( s_i \) (\( 0 \leq i \leq n - 2t \)). In particular, \((H_{Y(t)} + J_{t+1})/J_{t+1}\) is a quotient of the Hecke algebra of type \( M_{Y(t)} \).

But, its rank is equal to \(|W(M_{Y(t)})|\) which is the Hecke algebra dimension, and so \((H_{Y(t)} + J_{t+1})/J_{t+1}\) is isomorphic to the Hecke algebra of type \( M_{Y(t)} \).

(ii). In view of Corollary 7.2 and Proposition 1.5 \( b_{B,n}H_{Y(t)}b_{B,n} + J_{t+1} \) is the linear span of \( J_{t+1} \) and all monomials \( x \in B(D_n) \) such that \( \mu(x)(\emptyset) = B \) and \( \mu(x)^\text{op}(\emptyset) = B' \). But \( x = g_{B,n}e_{Y,t} \) satisfies \( \mu(x)(\emptyset) = r_i B \) and \( \mu(x)^\text{op}(\emptyset) = Y(t) \), so \( g_{B,n}e_{Y,t} \in b_{r_i,n}H_{Y,t} + J_{t+1} \).

Similarly, \( \mu(e_{B,n}e_{Y,t}(\emptyset) = \mu(e_{B,n}e_{Y,t}(\emptyset) = e_i B \) always contains a member \( B' \), say, of \( W_B \), and \( \mu(e_{B,n}e_{Y,t}(\emptyset = e_{Y,t}(\pi(a_{B,n}))^\text{op}(\emptyset) = Y(t) \), so \( e_{B,n}e_{Y,t} \in b_{r_i,n}H_{Y,t} + J_{t+1} \). Here if \( \alpha \perp B \) the expression is in \( J_{t+1} \).

(iii). It is readily verified that each \( s_i \) is fixed under opposition. As the opposite of a minimal expression in the \( s_i \) is again a minimal expression, \( \rho(U_{Y(t)}) \) is invariant under opposition. Hence, so is \( H_{Y(t)} \). \( \Box \)

We now give the cell datum for \( A = B(D_n) \otimes_R S \). View \( A_{n-1} \) as the subdiagram of \( D_n \) on the nodes 2, \ldots, \( n \). As an algebra over \( S \), the ideal \( \Theta' \) of \( A \) generated by \( e_1 e_2 \) is isomorphic to the ideal of \( B(A_{n-1}) \otimes_R S \) generated by \( e_2 \); see Proposition 6.3.

The ideal generated by \( e_2 \) is a cellular algebra as \( B(A_{n-1}) \) is cellular by [28, Theorem 3.11] and it inherits the cellular structure from that of \( B(A_{n-1}) \). In fact, it corresponds to the ideals with cell datum associated with partitions of \( n - 2t \) for \( 1 \leq t \leq \lfloor n/2 \rfloor \).

Let \( (\Lambda_\theta, T_\theta, C_\theta, \ast_\theta) \) be the cell datum for \( \Theta' \). It is clear from [28, Theorem 3.11] that \( \ast_\theta \) coincides with the restriction to \( \Theta' \) of the map \( \ast \). Moreover, the elements \( g_1 - g_2 \) and \( e_1 - e_2 \) are in the kernel of the action of \( A \) on \( \Theta' \) by left multiplication, as well as by right multiplication.

For \( 0 \leq t \leq \lfloor n/2 \rfloor \) we let \( (\Lambda_t, T_t, C_t, \ast_t) \) be the cell datum for the Hecke algebra \( H_{Y(t)} \) mod \( J_{t+1} \) of type \( M_{Y(t)} \) (see Corollary 8.6(i)) with \( \ast_t \) the restriction to \( H_{Y(t)} \) of \( \ast \). If \( n = 2t \), there is another copy needed which we denote \( (\Lambda_{n/2}', T_{n/2}', C_{n/2}', \ast_{n/2}') \); it corresponds to the admissible set \( Y(t) \). By [13], these cell data are known to exist if \( \frac{1}{2} \in S \). We take the values of \( C_t \) to be in \( H_{Y(t)} \).

The poset \( \Lambda \) is the disjoint union of \( \Lambda_\theta \) together with the posets \( \Lambda_t \) of the cell data for the various Hecke algebras \( H_{Y(t)} \) mod \( J_{t+1} \), as well as \( \Lambda_{n/2}' \) if \( n \) is even. We make \( \Lambda \) into a poset as follows. For a fixed \( t \) or \( \theta \) it is already a poset, and we keep the same partial order. Furthermore, any element of \( \Lambda_t \) is greater than any element of \( \Lambda_s \) if \( t < s \). In particular the elements of \( \Lambda_\theta \) are greater than the elements of \( \Lambda_t \) for any \( t \geq 1 \). Moreover, if \( n \) is even, any element of \( \Lambda_{n/2}' \) is smaller than any element of \( \Lambda_t \) for \( t < n/2 \). Finally, we decree that any element of \( \Lambda_\theta \) is smaller than any element of \( \Lambda_t \) (\( 0 \leq t \leq n/2 \)) or \( \Lambda_{n/2}' \).
Let \( t \in \{0, \ldots, \lfloor n/2 \rfloor \} \). For \( \lambda \in \Lambda_t \), we set \( T(\lambda) = WB_Y(\lambda) \times T_1(\lambda) \) and, if \( n \) is even, for \( \lambda \in \Lambda'_{n/2} \), we set \( T(\lambda) = WB_Y(\lambda) \times T'_{n/2}(\lambda) \). For \( \lambda \in \Lambda_\emptyset \), we set \( T(\lambda) = T_\emptyset(\lambda) \). This determines \( T \).

We define \( C \) as follows. For \( t \in \{0, \ldots, \lfloor n/2 \rfloor \} \), \( \lambda \in \Lambda_t \), and \( (B, x), (B', y) \in T(\lambda) \), we have

\[
C((B, x), (B', y)) = b_{B,n}C_t(x, y)b_{B',n}^{\text{op}}.
\]

Similarly on \( \Lambda'_{n/2} \times \Lambda'_{n/2} \). For \( \lambda \in \Lambda_\emptyset \), the map \( C | T(\lambda) \times T(\lambda) \) is just \( C_\emptyset \).

Since we have already defined \( \ast \) by the opposition map, this concludes the definition of \((\Lambda, T, C, \ast)\). We next verify the conditions (C1), (C2), (C3).

(C1). The map \( C \) has been chosen so that its image is an \( S \)-basis of \( \Theta' \) (the image of \( C_\emptyset \)), joint with the set of elements \( b_{B,n}C_t(x, y)b_{B',n}^{\text{op}} \) for \( B, B' \in WB_Y(\lambda) \) and \( C_t(x, y) \) running through a basis of \( H_Y(t) \), and \( b_{B,n}C'_{n/2}(x, y)b_{B',n}^{\text{op}} \) for \( B, B' \in WB_Y(\lambda) \) and \( C'_{n/2}(x, y) \) running through a basis of \( H_Y(\lambda) \). By Corollary 7.2, this implies that the image of \( C \) is a basis of \( A \). Injectivity of \( C \) follows from injectivity of \( C_t \), \( C_t \) (0 \( \leq t \leq n/2 \)), \( C'_t \) if \( n \) is even, and Theorem 11 which guarantees that no collapses of dimensions of the individual parts occur.

(C2). Clearly, \( \ast \) is an \( S \)-linear anti-involution. Let \( t \in \{0, \ldots, \lfloor n/2 \rfloor \} \), \( \lambda \in \Lambda_t \), and \( (B, x), (B', y) \in T(\lambda) \). Then \( (b_{B,n}C_t(x, y)b_{B',n}^{\text{op}})^{\ast} = b_{B',n}C_t(x, y)b_{B,n}^{\text{op}} \), so, in order to establish \( (C((B, x), (B', y)))^\ast = C((B', y), (B, x)) \), it suffices to verify that \( C_t(x, y)^{\text{op}} \) coincides with \( C_t(y, x) \). Now \( \ast \) on \( H_Y(t) \) modulo \( J_{t+1} \) coincides with opposition, so modulo \( J_{t+1} \) we have \( C_t(x, y)^{\text{op}} = C_t(x, y)^{\ast} = C_t(y, x) \) by the cellularity of \((\Lambda_t, T_t, C_t, \ast_t)\). On the other hand, as \( H_Y(t) \) is invariant under opposition, see Corollary 5.6.2, and contains the values of \( C_t \), it contains \( C_t(x, y)^{\text{op}} - C_t(y, x) \), so \( C_t(x, y)^{\text{op}} - C_t(y, x) \in H_Y(t) \cap J_{t+1} = \{ 0 \}\), whence \( C_t(x, y)^{\text{op}} = C_t(y, x) \), as required.

The case of \( \lambda \in \Lambda'_{n/2} \) for \( n \) even is similar. If \( \lambda \in \Lambda_\emptyset \) and \( x, y \in T(\lambda) \), then \( C(x, y)^{\ast} = C(y, x) \) is immediate from the cellularity of \((\Lambda_\emptyset, T_\emptyset, C_\emptyset, \ast_\emptyset)\).

(C3). Let \( \lambda \in \Lambda_t \) and \( (B, x), (B', y) \in T(\lambda) \). Fix \( i \in \{1, \ldots, n\} \). It clearly suffices to prove the formulas for a running over the generators \( g_i \) and \( e_i \) of \( B(D_n) \).

By choice of \( C_t \), we have \( C_t(x, y) \in H_Y(t) \), and, see Proposition 8.4(i), \( C_t(x, y) = \rho(e_{Y(t)})C_{t}(x, y) \). According to Corollary 5.6(ii), there is \( z_{B,i} \in H_Y(t) \), depending only on \( B \) and \( i \), such that \( g_{B,n}\rho(e_{Y(t)}) \in b_{g_{B,n}z_{B,i} + J_{i+1}} \). As \((\Lambda_t, T_t, C_t, \ast_t)\) is a cell datum for \( H_Y(t) \) mod \( J_{i+1} \), for each \( u \in T_t(\lambda) \), there are \( \nu_t(u, B, x) \in S \), independent of \( B' \) and \( y \), such that

\[
z_{B,i}C_t(x, y) \in \sum_{u \in T_t(\lambda)} \nu_t(u, B, x)C_t(u, y) + (H_Y(t))_{\lambda} + J_{i+1}.
\]

Since both \((H_Y(t))_{\lambda} \) and \( J_{i+1} \) are contained in \( A_{\lambda} \), we find

\[
g_{B,n}C((B, x), (B', y)) = g_{B,n}\rho(e_{Y(t)})C_t(x, y)b_{B',n}^{\text{op}} \in b_{r_{B,n}z_{B,i}C_t(x, y)}b_{B',n}^{\text{op}} + A_{\lambda}
\]

\[
= \sum_{u \in T_t(\lambda)} \nu_t(u, B, x)b_{r_{B,n}C_t(u, y)}b_{B',n}^{\text{op}} + A_{\lambda}
\]

\[
= \sum_{u \in T_t(\lambda)} \nu_t(u, B, x)C((r_{B,u}, (B', y)) + A_{\lambda},
\]
as required.
Rewriting (RSrr) to \( e_i = \text{lm}^{-1}(g_i^2 + mg_i - 1) \), we see that, if \( m^{-1} \in S \), the proper behavior of the cell data under left multiplication by \( e_i \) is taken care of by the above formulae for \( g_i \). A proof in full generality can be given that is similar to the above proof for \( g_i \) using Corollary 5.6(ii).
For \( \lambda \in \Lambda_n \), the formulae are straight from those for \( \Theta' \) as \( g_1 a = g_2 a \) and \( e_1 a = e_2 a \) for each \( a \in \Theta' \).
This establishes that \((\Lambda_n, T, C, \ast)\) is a cell datum for \( X \) and so completes the proof of Theorem 1.2.
Alternatively, the information we have provided shows \( B(D_n) \) is an iterated inflation of Hecke algebras of type \( D_n, D_{n-2t}, \) and \( A_{n-1-2s} \) for \( s, t \geq 1 \) and so are cellular by 19.

9. Discussion

The following consequence of Corollary 6.12 will be of use in \([8]\). It involves the products \( A_{B,n} = a_{B,n} e_Y \) where \( B \in WBY \).

**Theorem 9.1.** Let \( Y \in \mathcal{Y} \). For each \( B \in WBY \) there is, up to homogeneous equivalence and powers of \( \delta \), a unique word \( A_{B,n} \) in \( F_n e_Y \) satisfying the following three properties for each node \( i \) of \( D_n \).

(i) \( r_i A_{B,n} \sim A_{r_i B,n} h \) for some \( h \in U_Y \). Furthermore, if \( r_i B > B \), then \( h \) is the identity \( e_Y \) of \( U_Y \).
(ii) If \( |e_i B| = |B| \), then \( e_i A_{B,n} \sim A_{e_i B,n} h \) for some \( h \in \delta^2 U_Y \) and \( \text{ht}(e_i B) \leq \text{ht}(B) \).
(iii) If \( |e_i B| > |B| \), then \( e_i A_{B,n} \) reduces to an element of \( BrM(D_n)e_U BrM(D_n) \) for some set of nodes \( U \) strictly containing \( Y \).

In \([6]\) Proposition 3.1] it is shown that there is a natural order on each \( W \)-orbit in \( \mathcal{A} \), and in fact, \([6]\) Corollary 3.6], each such orbit has a unique maximal element under this order. The ordering is also involved in a notion of height for elements of \( \mathcal{A} \), denoted \( \text{ht}(B) \) for \( B \in \mathcal{A} \), which satisfies \( \text{ht}(B) < \text{ht}(C) \) whenever \( B \) and \( C \) are in the same \( W \)-orbit in \( \mathcal{A} \) and satisfy \( B < C \). Moreover, if \( r_i B > B \), then \( \text{ht}(r_i B) = \text{ht}(B) + 1 \). There are certain minimal elements \( Y \in \mathcal{A} \) (such as the sets \( B_Y \) for \( Y \in \mathcal{Y} \) described above). Then \( \text{ht}(B) \) will the distance to the maximal element in the Hasse diagram of the part of the poset \( WB = WBY \). In particular, \( \text{ht}(B_Y) = 0 \). The word \( A_{B,n} \) has height \( \text{ht}(B) \) and moves \( \emptyset \) to \( B \) in the left action: \( A_{B,n}(\emptyset) = B \).

The words \( A_{B,n} \) are as given by Notation 6.10 using Lemma 6.9 and involve an ordering of the roots of \( B \). Height considerations as above give an algorithm for choosing a representative for \( A_{B,n} \). To begin, pick \( \beta_n \) to be a root of smallest height in \( B \). Then \( \beta_{n-2} \) should be a root of smallest height in \( a_{\beta_{n-2}} B \setminus \{\alpha_n\} \) in case \( B \in WBY(t) \). Continue at each step picking the next root \( \beta_{n-2s} \) as one of smallest height from the roots remaining. Similarly for other \( Y \in \mathcal{Y} \).

An alternative proof of the results of this paper, using the methods of \([8]\) is possible.

The proof in that paper deals with the case \( M = E_n \) \((n = 6, 7, 8) \) and involves a search of a finite number of finite posets. The search can be avoided in the case \( M = D_n \) by using the specific structure of the root system and induction on \( n \).

In \([8]\), the definition of \( A_{B,n} \) (which is denoted \( a_B \) there) is given by the following algorithm which need not be the same as the one above.
Algorithm 9.2. Given $B \in \mathcal{A}$, determine a word $A_{B,n}$ of minimal height with $A_{B,n}(\emptyset) = B$.

(i) If the number of simple nodes in $B$ is $t$, then $A_{B,n}$ is a product of $e_i$ which moves these simple nodes to $Y$ as described in [8].

(ii) If $r_k B < B$ for some node $k$, then $A_{B,n} = r_k A_{r_k B,n}$.

(iii) Otherwise, there are adjacent nodes $j, k$ with $\alpha_j \in B$; then $A_{B,n} = e_j A_{e_k B,n}$ where $A_{e_k B,n}$ has been defined inductively. Here $e_k B = r_j r_k B$, $e_j e_k B = B$, and $\text{ht}(e_k B) = \text{ht}(B)$.

The main result of this paper concerns an upper bound for the BMW algebra, given by a presentation. A lower bound, as can be seen in the proof of the main theorem, is in [4]. In particular, the current results finish the proof of the main theorem in the paper [7] on the tangle algebra $\mathbf{KT}(D_n)$, which gives a topological depiction of $B(D_n)$.

On the level of the Brauer algebra, for a monomial $a$, the admissible set $B = a(\emptyset)$ determines the connections of the horizontal strands at the top in the following way: if $\varepsilon_i - \varepsilon_j$ belongs to $B$, then there is a horizontal strand from top node $i$ to top node $j$ that does not go around the pole. If $\varepsilon_i + \varepsilon_j$ belongs to $B$, then there is a horizontal strand from top node $i$ to top node $j$ that goes around the pole. If $\varepsilon_i - \varepsilon_j$ and $\varepsilon_i + \varepsilon_j$ both belong to $B$, then $\Theta$, the pair of loops going around the pole as defined in [7], belongs to the tangle. In addition, the paper [7] gives an alternative proof of the lower bound on the rank of $B(D_n)$.

Furthermore, the ideal $\Theta'$ in $B(D_n)$ has a nice interpretation in the tangle algebra $\mathbf{KT}(D_n)$, where they are ordinary tangles with no loops around the pole and with coefficient $\Theta$, as described in [7]. Here there must be at least one horizontal strand at the top and one at the bottom. These tangles span the ideal corresponding to $\mu^{-1}(Q)$, for $Q$ as in Proposition 6.3. This ideal is easily seen to be the ideal in $B(A_{n-1})$ identified in Section 7.
