Experimental

Materials. NaCl and concentrated sulfuric acid were used as received from Macron Chemicals. Crystalline phenol (99.6%) and Na$_2$C$_2$O$_4$ were purchased from J.T. Baker. Total Protein Reagent, Folin-Ciocalteu’s phenol reagent, protein standard (bovin serum albumin), TiOSO$_4$, H$_2$IrCl$_6$, [O$_2$CCH$_2$C(OH)(CO$_2$)CH$_2$CO$_2$]Bi, Bi$_2$O$_3$, SnCl$_4$, and TaCl$_5$ were received from Sigma Aldrich. Chemical oxygen demand (COD) digestion solution, COD standard solution (potassium acid phthalate), total nitrogen (TN) reagent set, DPD total chlorine reagent powder, chlorine standard solution were received from Hach. Jack Bean Urease was provided by the Worthington Biochemical Corporation. All other chemicals were supplied by Mallinckrodt. Ti metal sheet (Ti-Gr.2 sheet, 0.50 mm thick) was purchased from ThyssenKrupp Materials. All electrolyte and standard solutions were prepared in MilliQ water (18.2 MO cm) from a Millipore Milli-Q gradient water purification system.

BiO$_x$/TiO$_2$ electrode preparation. A Ti metal sheet (0.5 mm thick) was sand-blasted with SiC paper (120 – 240 grits) and degreased with acetone. The precursor solution for the anti-passivation layer was prepared as 73 mM H$_2$IrCl$_6$ with 27 mM TaCl$_5$ in 4 M HCl solution. Both sides of pretreated Ti support were brushed by the precursor and annealed at 525 °C for an hour. This procedure was repeated for 5 times with the same annealing temperature for 10 minutes duration. A sealing coat was deposited twice by painting 225 mM SnCl$_4$ and 12.5 mM Bi$_2$O$_3$ in 0.5 M HCl solution and baking at 425 °C for 10 minutes. Precipitates from dissolving 10 mmol Bi$_2$O$_3$ and 0.48 mol TiOSO$_4$ in 1.2 M Na$_2$CO$_3$ (1 L) were calcined at 830 °C for 45 minutes to
produce bismuth oxide doped titanium dioxide (BiO\textsubscript{x}/TiO\textsubscript{2}) nanoparticles. The precursor for the BiO\textsubscript{x}/TiO\textsubscript{2} thin film (overcoat solution) was 160 mM Ti(OCH\textsubscript{2}CH\textsubscript{2}O)\textsubscript{2} (i.e., the preparation details are described in elsewhere) with 80 mM [O\textsubscript{2}CCH\textsubscript{2}C(OH)(CO\textsubscript{2})CH\textsubscript{2}CO\textsubscript{2}]Bi in a 0.24 M NH\textsubscript{4}OH solution. To prepare the slurry deposition layer, BiO\textsubscript{x}/TiO\textsubscript{2} particles dispersed in MilliQ water (3 M metal concentration) were brushed on air dried; after this step a 25-fold diluted overcoat solution was sequentially pasted on to the surface. The slurry deposit was baked on at 250 for 5 minutes; this procedure was repeated for 7 times. In the final sequence, a thin film of BiO\textsubscript{x}/TiO\textsubscript{2} deposit was made by repetitive sealing with overcoat solution annealed at 250 °C (4 times) and then at 450 °C (2 times).

**Electrochemical methods.** Before all electrochemical experiments, the electrodes were rinsed with acetone and large amount of MilliQ water. The electrode module was allowed to equilibrate with the electrolyte solution in an open circuit for 1 hr while monitoring the open circuit potential of anode and cathode. As a routine procedure, the pH, conductivity and the ohmic resistance between anode and reference electrode (R) were measured before and after the electrochemical experiments. The R was measured by current interruption method with current bias of 100 mA. For the chrono-voltammetric data collection, the current intensity (J) was averaged from 400 to 500 seconds. The variation of current density after 500 seconds was not significant, since the p-values of paired t-test between averaged current from 400 to 500 seconds and from 500 to 1800 seconds were always larger than 0.05.

**Model septic tank effluent preparation.** The COD degradation during the anaerobic incubation
followed an exponential decay trend, where initial decomposition of macro-molecules was followed by mineralization of organics with exponential growth of microorganisms, initially presented in domestic wastewater (DWW). Urea was hydrolyzed to give ammonium ion enzymatically using urease; this resulted in an increase of the pH of the model septic tank effluents (STEs) up to 9. The increase in pH resulted in a considerable amount of precipitation of minerals including magnesium ammonium phosphate (struvite). The supernatant of the collected DWW and prepared STEs was used in the experiments to minimize the effects of particulate matters.

**Analyses.** COD was measured with standard digestion kits with a low detection range (3 – 150 mg L⁻¹); the kits were prepared in order to eliminate the interference of the ammonium ion in the COD analysis by controlling the kinetics for ammonium and COD oxidation steps separately. Samples were diluted to adjust the chloride concentration far below the interference range (2,000 mg L⁻¹) as suggested by the digestion kit supplier (Hach, USA). For the Dionex DX-500 Ion Chromatography (IC) system, hypochlorite appeared to have a peak at a retention time identical to the chloride ion with superimposable calibration curves. Since the hypochlorite would be detected both in the IC analysis and total chlorine (Cl<sub>DPD</sub>) analysis, the sum of [Cl⁻], [Cl<sub>DPD</sub>] and [ClO₃⁻] exceeded the initial chloride concentration, particularly for the electrolysis in pure NaCl solution. In this case, [Cl⁻] was calibrated by subtracting the difference which corresponds to [ClO⁻]. For urea measurement, 5 mL of diluted samples in 15 mL conical tubes were added by 2 mL of urease solution (63.1 mg L⁻¹) and incubated in water bath (50 °C) for 20 min. Treated samples were cooled down in room temperature (RT) for IC analysis. Urea measurements were
performed only for the intact electrolyte before the electrolysis due to the interference of free chlorine. In phenol-sulfuric acid method, 0.4 mL samples in glass tubes were mixed with 0.4 mL phenol solution (5 W/V%) and 2 mL sulfuric acids (95%) to measure the absorbance at 470 nm after reaction for 30 min at RT. For protein measurement, 0.5 mL samples were introduced to 2.5 mL total protein reagent in 15 mL conical tubes with gentle inversion for several times. After reaction for 10 min at RT, twofold diluted Folin-Ciocalteu’s phenol reagent of 0.2 mL was added with vigorous mixing. With further holding at RT for 30 min, the absorbance of the supernatant was measured at 600 nm. NH₄Cl, NaOCl, NaClO₃, NaNO₂, NaNO₃, HCOONa, Na₂C₂O₄, CH₃COONa, MgSO₄ and CaCl₂ were used as standards with proper concentration range for the IC analysis. Potassium acid phthalate, NH₄Cl, chlorine, bovine serum albumin and glucose solution were used as a standard for COD, TN, ClDPD, protein and carbohydrate analysis, respectively.

**Kinetic Model Derivation**

**Kinetic equations in the absence of oxidizable pollutants.**

\[
\frac{d[M oxide(\text{ClO}^-)]}{dt} = k_{4a}[M oxide_{x+1}][\text{Cl}^-] - k_{4b}[M oxide][\text{ClO}^-][\text{Cl}^-][H^+]^2 = 0 \tag{S1}
\]

\[
\frac{d[\text{Cl}^-]}{dt} = -k_{4a}[M oxide_{x+1}][\text{Cl}^-] - k_{4b}[M oxide][\text{ClO}^-][\text{Cl}^-][H^+]^2 + k_{5a}[Cl_2] - k_{-5a}[\text{HOCl}][\text{Cl}^-][H^+] \tag{S2}
\]

\[
\frac{d[Cl_2]}{dt} = k_{4a}[M oxide_{x+1}][\text{Cl}^-] - k_{5a}[Cl_2] + k_{-5a}[\text{HOCl}][\text{Cl}^-][H^+] = 0 \tag{S3}
\]

\[
\frac{d[\text{HOCl}]}{dt} = k_{5a}[Cl_2] + k_{-5a}[\text{HOCl}][\text{Cl}^-][H^+] - k_{5b}[\text{HOCl}] + k_{-5b}[\text{ClO}^-][H^+] - k_{6b}[M oxide_{x+1}]^2[\text{HOCl}] \tag{S4}
\]
\[
\frac{d[Clo^-]}{dt} = k_{5b}[HOCl] - k_{-5b}[ClO^-][H^+] - k_{6a}[MO_{x+1}]^2[ClO^-] \quad (S5)
\]

\[
\frac{d[ClO^-]}{dt} = k_{6a}[MO_{x+1}]^2[ClO^-] + k_{6b}[MO_{x+1}]^2[HOCl] \quad (S6)
\]

Eq. S1 implies a pseudo-steady-state assumption for the surface bound ClO\(^-\), while Eq. S3 is based on the negligible amount of Cl\(_2\) at circum-neutral pH. Assuming that active sites are saturated at high current densities (quasi-constant \([MO_{x+1}]\)), we use Eq. S1 and Eq. S3 in Eq. S2 to obtain

\[
\frac{d[Cl^-]}{dt} = -k_{4a}[MO_{x+1}][Cl^-] = -k_4^{eff} [Cl^-] \quad (7)
\]

By denoting \([FC] = [Cl_2] + [HOCl] + [ClO^-]\), Eq. S3-S5 gives

\[
\frac{d[FC]}{dt} = k_{4a}[MO_{x+1}][Cl^-] - k_{6a}[MO_{x+1}]^2[FC] = k_4^{eff} [Cl^-] - k_6^{eff} [FC] \quad (8)
\]

Assuming that \(k_{6a}\) is comparable to \(k_{6b}\) and \([FC] \sim [HOCl] + [ClO^-]\) at circum-neutral pH,

\[
\frac{d[ClO^-]}{dt} = k_{6a}[MO_{x+1}]^2[FC] = k_6^{eff} [FC] \quad (9)
\]

**Instantaneous Current Efficiency (ICE) for free chlorine (FC) and chlorate without the presence of organics.** Substituting the analytical solutions of Eq. 7 – 9 to Eq. 10 yields,

\[
ICE_{FC} = \frac{2[k_4^{eff} \exp(-k_4^{eff}t) - k_4^{eff}k_6^{eff} \exp(-k_4^{eff}t) - \exp(-k_6^{eff}t)]}{2k_3^{eff} + 2k_4^{eff} \exp(-k_4^{eff}t) + 4k_4^{eff}k_6^{eff} \exp(-k_4^{eff}t) - \exp(-k_6^{eff}t)} \quad (S8)
\]

Where, \([Cl^-]_0\) denotes the initial chloride concentration.

Supporting Information Cho et al. (6/16)
When \( t \to 0 \), \( ICE_{FC} = \frac{k_4^{eff}}{k_3^{eff} + k_4^{eff} [Cl^-]_0} \) \hspace{1cm} \text{(S9)}

Similarly, the instantaneous current efficiency for chlorate formation is expressed as

\[
ICE_{ClO_3^-} = \frac{\frac{6k_4^{eff}k_6^{eff}}{k_6^{eff} - k_4^{eff}}[exp(-k_4^{eff}t) - exp(-k_6^{eff}t)]}{2k_5^{eff} + 2k_4^{eff} exp(-k_4^{eff}t) + \frac{4k_4^{eff}k_6^{eff}}{k_6^{eff} - k_4^{eff}}[exp(-k_4^{eff}t) - exp(-k_6^{eff}t)]} \hspace{1cm} \text{(S10)}
\]

**Kinetic equations in the presence of pollutants.** The governing equations for chloride and FC with the presence of pollutants are derived by modifying Eq. 7 and 8 as:

\[
\frac{d[Cl^-]}{dt} = -k_4^{eff} [Cl^-] + k_{13} [FC][COD] + (3k_{14} + 4k_{15})[FC][NH_4^+] \hspace{1cm} \text{(S11)}
\]

\[
\frac{d[FC]}{dt} = k_4^{eff} [Cl^-] - k_6^{eff} [FC] - k_{13} [FC][COD] - (3k_{14} + 4k_{15})[FC][NH_4^+] \hspace{1cm} \text{(16)}
\]

By treating the FC mass balance analyses for the bulk-phase and the electrode boundary layer separately, we employ pseudo-steady-state approximations for the FC to give

\[
\frac{d[FC]^A_{SS}}{dt} = k_4^{eff} [Cl^-] - k_6^{eff} [FC]^A_{SS} - \frac{k_m^{FC}}{\delta} ([FC]^A_{SS} - [FC]^B_{SS}) = 0 \hspace{1cm} \text{(S12)}
\]

\[
\frac{d[FC]^B_{SS}}{dt} = \frac{k_m^{FC}}{\delta} ([FC]^A_{SS} - [FC]^B_{SS}) - [FC]^B_{SS} [k_{13} [COD] + (3k_{14} + 4k_{15})[NH_4^+]] = 0 \hspace{1cm} \text{(S13)}
\]

Where, [FC]^A_{SS} and [FC]^B_{SS} are quasi-steady-state FC concentration in the anode vicinity and in bulk, \( k_m^{FC} \) is the mass transfer coefficient for the FC and \( \delta \) is the depth of boundary layer. Since \( [FC]^A_{SS} >> [FC]^B_{SS} \), the solutions of Eq. S12 and S13 are reduced to
\[
[FC]^A_{SS} = \frac{k_4^{eff}[Cl^-]}{k_6^{eff} + k_m^{FC}/\delta} \equiv C_{[FC]^A_{SS}}[Cl^-] \tag{S14}
\]

\[
[FC]^B_{SS} = \frac{\left(k_m^{FC}/\delta\right)k_4^{eff}[Cl^-]}{\left(k_6^{eff} + k_m^{FC}/\delta\right)\left(k_{13}[COD] + (3k_{14} + 4k_{15})[NH_4^+]\right)} \equiv \frac{C_{[FC]^B_{SS}}[Cl^-]}{\left(k_{13}[COD] + (3k_{14} + 4k_{15})[NH_4^+]\right)} \tag{S15}
\]

Also, the mass balance equation for chloride (Eq. S11) and chlorate (Eq. 9) are modified as

\[
\frac{d[Cl^-]}{dt} = -k_4^{eff}[Cl^-] + k_{13}[FC]^B_{SS}[COD] + (3k_{14} + 4k_{15})[FC]^B_{SS}[NH_4^+] \tag{S16}
\]

\[
\frac{d[ClO_3^-]}{dt} = k_6^{eff}[FC]^A_{SS} \tag{S17}
\]

**Instantaneous Current Efficiency (ICE) for COD degradation.** Substituting Eq. S14 and S15 into Eqs. 21 – 24 gives

\[
ICE_{COD} = \frac{4C_{[FC]^B_{SS}}^{\frac{2k_3^{eff}}{[Cl^-]} + 2k_4^{eff} + 4C_{[FC]^A_{SS}}^{k_6^{eff}}}}{\left(1 + \frac{3k_{14} + 4k_{15}}{3k_{14}}\right)} \tag{S18}
\]

\[
ICE_{N_2} = \frac{4C_{[FC]^B_{SS}}^{\frac{2k_3^{eff}}{[Cl^-]} + 2k_4^{eff} + 4C_{[FC]^A_{SS}}^{k_6^{eff}}}}{\left(1 + \frac{3k_{14} + 4k_{15} + k_{13}[COD]}{3k_{14} + 4k_{15} + k_{13}[COD]}\right)} \tag{S19}
\]

\[
ICE_{NO_3^-} = \frac{4C_{[FC]^B_{SS}}^{\frac{2k_3^{eff}}{[Cl^-]} + 2k_4^{eff} + 4C_{[FC]^A_{SS}}^{k_6^{eff}}}}{\left(1 + \frac{3k_{14} + 4k_{15} + k_{13}[COD]}{4k_{15} + 3k_{14}}\right)} \tag{S20}
\]

\[
ICE_{ClO_3^-} = \frac{6C_{[FC]^A_{SS}}^{k_{6}^{eff}}}{\frac{2k_3^{eff}}{[Cl^-]} + 2k_4^{eff} + 4C_{[FC]^A_{SS}}^{k_6^{eff}}} \tag{S21}
\]
