Semiclassical ET theory predicts that reactants will have identical configurations at the transition state for an electron-exchange reaction. For the electron exchange reaction between Fc and Fc$^+$ in the gas phase, this configuration is defined as $Q^\dagger$ (Figure S1). The energy required to reach this configuration is equal to $\lambda_1 + \lambda_2$, where $k$ is an arbitrary force constant. The transition state configuration ($Q^\dagger$) corresponds to a minimum value of $\lambda_1 + \lambda_2$, found by differentiation:

$$\lambda_1 = \frac{1}{2} k (Q - Q_o)^2$$

$$\lambda_2 = \frac{1}{2} k (Q - (Q + \delta_Q))^2$$

$Q^\dagger = Q_o + \frac{1}{2} \delta_Q$

The ionization energy at $Q^\dagger$ is given by:

$$IE(Q^\dagger) = E_{00} + \frac{1}{2} k (Q^\dagger - (Q_o + \delta_Q))^2 - \frac{1}{2} k (Q^\dagger - Q_o)^2.$$  

Simplification gives the following result:

$$IE(Q^\dagger) = E_{00}$$

Hence, the Fc ionization energy at the electron-exchange transition state is best approximated by the adiabatic ionization energy.
