Classical Electrodynamics in Terms of Direct Interparticle Action

JOHN ARCHIBALD WHEELER and RICHARD PHILIPS FEYNMAN
Princeton University, Princeton, New Jersey

"... the energy tensor can be regarded only as a provisional means of representing matter.
In reality, matter consists of electrically charged particles..."7

INTRODUCTION AND SUMMARY

MANY of our present hopes to understand the behavior of matter and energy rely upon the notion of field. Consequently it may be appropriate to re-examine critically the origin and use of this century-old concept. This idea developed in the study of classical electromagnetism at a time when it was considered appropriate to treat electric charge as a continuous substance. It is not obvious that general acceptance in the early 1800’s of the principle of the atomicity of electric charge would have led to the field concept in its present form. Is it after all essential in classical field theory to require that a particle act upon itself? Of quantum theories of fields and their possibilities we hardly know enough to demand on quantum grounds that such a direct self-interaction should exist. Quantum theory defines those possibilities of measurement which are consistent with the principle of complementarity, but the measuring devices themselves after all necessarily make use of classical concepts to specify the quantity measured.4 For this reason it is appropriate to begin a re-analysis of the field concept by returning to classical electrodynamics. We therefore propose here to go back to the great basic problem of classical physics—the motion of a system of charged particles under the influence of electromagnetic forces—and to inquire what description of the interactions and motions is possible which is at the same time (1) well defined (2) economical in postulates and (3) in agreement with experience.

We conclude that these requirements are satisfied by the theory of action at a distance of Schwarzschild,6 Tetrode,4 and Fokker.7 In this description of nature no direct use is made of the notion of field. Each particle moves in compliance with the principle of stationarity.

\[ J = \sum \frac{1}{2} \left( \sum m_a \int (-da_a da^a) + \sum (e_a e_b / c) \right) \]

\[ \times \int \int \delta(ab, b') (da_a db_a) = \text{extremum.} \] (1)

All of mechanics and electrodynamics is contained in this single variational principle.

However unfamiliar this direct interparticle treatment compared to the electrodynamics of Maxwell and Lorentz, it deals with the same problems, talks about the same charges, considers the interaction of the same current elements, obtains the same capacities, predicts the same inductances and yields the same physical conclusions. Consequently action at a distance must have a close connection with field theory. But never does it consider the action of a charge on itself. The theory of direct interparticle action is equivalent, not

---

8 Here the letters \(a, b...\) denote the respective particles. Particle \(a\) has in c.g.s. units a mass of \(m_a\) grams, a charge of \(e_a\) franklins (e.s.u.), and at a given instant the coordinates \(a^a\) the three space coordinates, measured in cm.

Greek indices indicate places where a summation is understood to be carried out over the four values of a given label. The argument \(abob\) of the delta-function thus vanishes when and only when the locations of the two particles in space-time can be connected by a light ray. Here the delta-function \(\delta(x)\) is the usual symbolic operator defined by the conditions \(\delta(x) = 0\) when \(x \neq 0\) and \(\int_0^x \delta(x) dx = 1\). In the evaluation of the action, \(J\), from (1), the world lines of the several particles are considered to be known for all time; i.e., the coordinates \(a^\alpha\) are taken to be given functions of a single parameter, \(a\), which increases monotonically along the world line of the first particle; likewise for \(b, c, \text{etc.}\)

An arbitrary assumed motion of the particles is not in general in accord with the variation principle: a small change of the first order, \(a^\alpha(a), b^\beta(b), \text{...}\) in the world lines of the particles (this change here being limited for simplicity to any finite interval of time, and the length of this time interval later being increased without limit) produces in general a non-zero variation of the first order, \(\delta J\), in \(J\) itself. Only if all such first order variations away from the originally assumed motion produce no first order change in \(J\) is that originally assumed motion considered to satisfy the variation principle. It is such motions which are in this article concluded to be in agreement with experience.
to the usual field theory, but to a modified or \textit{adjunct field theory}, in which

(1) the motion of a given particle is determined by the sum of the fields produced by—or \textit{adjunct to}—every particle other than the given particle.
(2) the field adjunct to a given particle is uniquely determined by the motion of that particle, and is given by half the retarded plus half the advanced solution of the field equations of Maxwell for the point charge in question.

This description of nature differs from that given by the usual field theory in three respects:

1. There is no such concept as "the" field, an independent entity with degrees of freedom of its own.
2. There is no action of an elementary charge upon itself and consequently no problem of an infinity in the energy of the electromagnetic field.
3. The symmetry between past and future in the prescription for the fields is not a mere logical possibility, as in the usual theory, but a postutional requirement.

There is no circumstance of classical electrodynamics which compels us to accept the three excluded features of the usual field theory. Indeed, as regards the question of the action of a particle upon itself, there never was a consistent theory, but only the hope of a theory. It is therefore appropriate now and hereafter to formulate classical electrodynamics in terms of the adjunct field theory or the theory of direct interparticle action. The agreement of these two descriptions of nature with each other and with experience assures us that we arrive in this way at the \textit{natural} and \textit{self-consistent generalization} of Newtonian mechanics to the four-dimensional space of Lorentz and Einstein.

It is easy to see why no unified presentation of classical electrodynamics along these lines has yet been given, though the elements for such a description are all present in isolated form in the literature. The development of electromagnetic theory came before the era of relativity. Most minds were not prepared for the notion that interactions should be propagated with a certain characteristic speed, still less for the Newtonian instantaneous action at a distance.

Field theory taught gradually and over seven decades difficult lessons about constancy of light velocity, about relativity of space and time, about advanced and retarded forces, and in the end made possible by this circuitous route the theory of direct interparticle interaction which Gauss had hoped to achieve in one leap. On this route and historically important was Léonard\textsuperscript{11} and Wiechert's\textsuperscript{12} derivation from the equations of Maxwell of an expression for the elementary field generated by a point charge in an arbitrary state of motion. With this expression as starting point Schwarzschild arrived at a law of force between two point charges which made no reference to field quantities. Developed without benefit of the concept of relativity, and expressed in the inconvenient notation of the prerelativistic period, his equations of motion made no appeal to the physicists of the time. After the advent of relativity Schwarzschild's results were rederived independently by Tetrode and Fokker. These results are most conveniently summarized in Fokker's principle of stationary action of Eq. (1).

To investigate the consistency of the Schwarzschild-Tetrode-Fokker theory of direct interparticle interaction and its relation to field theory, we have first to

\textsuperscript{12} E. Wiechert, Archives Néerland (2) 5, 549 (1900); Ann. d Physik 4, 676 (1901). Compare these derivations in prerelativistic notation with that given for example by W. Heitler, \textit{The Quantum Theory of Radiation} (Oxford University Press, New York, 1944), second edition, p. 19, or A. Sommerfeld, Ann. d Physik 33, 668 (1910).
examine in the next section the paradox of advanced interactions. In the following section is recalled the derivation of the equations of motion from the variation principle. Next these equations of motion are shown to satisfy the principle of action and reaction as generalized to the non-instantaneous forces of a relativistic theory of action at a distance. In a subsequent section the corresponding formulation of the laws of conservation of energy and momentum is given. Finally the connection is established between these conservation laws and the field-theoretic description of a stress-energy tensor defined throughout space and time.

THE PARADOX OF ADVANCED ACTIONS

The greatest conceptual difficulty presented by the theory of direct interparticle interaction is the circumstance that it associates with the retarded action of \( a \) on \( b \), for example, an advanced action of \( b \) on \( a \). A description employing retarded forces alone would violate the law of action and reaction or, in mathematical terms, could not be derived from a single principle of stationary action.

Advanced actions appear to conflict both with experience and with elementary notions of causality. Experience refers not to the simple case of two charges, however, but to a universe containing a very large number of particles. In the limiting case of a universe in which all electromagnetic disturbances are ultimately absorbed it may be shown that the advanced fields combine in such a way as to make it appear—except for the phenomenon of radiative reaction—that each particle generates only the usual and well-verified retarded field. It is only necessary to make the natural postulate that we live in such a completely absorbing universe to escape the apparent contradiction between advanced potentials and observation.

In a universe consisting of a limited number of charged particles advanced effects occur explicitly. It is no objection if the character of physics under such idealized conditions conflicts with our experience. It is only required that the description should be logically self-consistent. In particular in analyzing the behavior of an idealized universe containing only a few particles we cannot introduce the human element as we know it into the systems under study. To do so would be to assume tacitly the possibility of a clean cut separation between the effects of past and future. This possibility is denied in a description of nature in which both advanced and retarded effects occur explicitly.

The apparent conflict with causality begins with the thought: If the present motion of \( a \) is affected by the future motion of \( b \), then the observation of \( a \) attributes a certain inevitability to the motion of \( b \). Is not this conclusion in direct conflict with our recognized ability to influence the future motion of \( b \)?

All essential elements of the general paradox appear in the following idealized example: Charged particles \( a \) and \( b \) are located in otherwise charge-free space at a distance of 5 light-hours. A clockwork mechanism is set to accelerate \( a \) at 6 p.m. Thereby \( b \) will be affected, not only at 11 p.m. via retarded effects, but also at 1 p.m. via advanced forces. This afternoon motion will cause \( a \) to suffer a premonitory movement at 8 a.m. Seeing this motion in the morning, we conclude the clockwork will go off in the evening. We return to the scene a few seconds before 6 p.m. and block the clockwork from acting on \( a \). But then why did \( a \) move in the morning?

To formulate the paradox acceptably, we have to eliminate human intervention. We therefore introduce a mechanism which saves charge \( a \) from a blow at 6 p.m. only if this particle performs the expected movement at 8 a.m. (Fig. 1). Our dilemma now is this: Is \( a \) hit in the evening or is it not? If it is, then it suffered a premonitory displacement at 8 a.m. which cut off the blow, so \( a \) is not struck at 6 p.m.! If it is not bumped at 6 p.m. there is no morning movement to cut off the blow and so in the evening \( a \) is jolted!

To resolve, we divide the problem into two parts: effect of past of \( a \) upon its future, and of future upon past. The two corresponding curves in Fig. 2 do not cross. We have no solution, because the action of the shutter on the pellet, of the future on the past, has been assumed discontinuous in character.

The paradox, and the case it presents against advanced potentials, evidently depends on the postulate that discontinuous forces can exist in nature. From a physical point of view we are led to make just the contrary assumption, that the influence of the future upon the past depends in a continuous manner upon the future configuration.

Our general assumption about continuity is explicitly verified in the present case. The action of shutter on pellet is not discontinuous. The pellet will strike the point \( S \) a glancing blow if the shutter lies only part way across its path (dashed curve in Fig. 2).

Of the problem of influence of future upon past, and past upon future, we now have in Fig. 2 a self-consistent solution: Charge \( a \) by late afternoon has moved a
very slight distance athwart the path of the pellet. Thus one second before 6 p.m. it receives a glancing blow in the counter-clockwise sense and at 6 p.m. a stronger acceleration in the clockwise direction. The accelerations received by a at these two moments are by electromagnetic interaction transmitted in reduced measure to b at 1 p.m. and back from b in yet greater attenuation to a. Thus this particle receives one second before 8 a.m. a certain counter-clockwise impulse and at 8 a.m. an opposite impulse. The net rotational momentum imparted to the lever is clockwise. It carries the point S in the course of 10 hours the necessary distance across the path of the pellet. The chain of action and reaction is completed. The paradox is resolved.

Generalizing, we conclude advanced and retarded interactions give a description of nature logically as acceptable and physically as completely deterministic as the Newtonian scheme of mechanics. In both forms of dynamics the distinction between cause and effect is pointless. With deterministic equations to describe the motion of a particle, the "proper cotime," defined in terms of a up to an unimportant additive constant by the equation $\delta \mathbf{a} = \delta \mathbf{a}/\delta a$, and dots derivatives with respect to the proper cotime. Introduce also the abbreviation

$$F_{m \mathbf{a}^{(b)}}(x) = \partial A_{m \mathbf{a}^{(b)}}(x)/\partial x^n - \partial A_{m \mathbf{a}^{(b)}}(x)/\partial x^n$$

(field at point $x$ due to $b$). The four-vector equation of motion takes a form,

$$m \mathbf{a} \delta \mathbf{a} = \epsilon_0 \sum_{b \neq a} \int F_{m \mathbf{a}^{(b)}}(a) \mathbf{a}$$

identical with that of Lorentz, with the following exceptions: self-actions are explicitly excluded; no fields act except those adjacent to the other particles; each such adjunct field is uniquely determined by the prescription of Eqs. (2) and (4).

Now we come to the well known proof that each adjunct field satisfies Maxwell's equations when for charge and current are introduced the appropriate expressions for the given particles. We employ Dirac's identity

$$A_n^{(b)}(x) = \epsilon_0 \int \delta(x_b x b x) dB_n(b)$$

for the density-current four-vector at point $x$ due to particle $b$, an obviously singular quantity, obeying certain evident conservation relations.

13. The electric field $E_b$ is $F_b = -F_{a \mathbf{a}}$ and the magnetic field $H_b$ is $F_{a \mathbf{a}} = -F_{a \mathbf{a}}$. Likewise in Eq. (8) $j_{a \mathbf{a}} = -j_{a \mathbf{a}}$ gives (1/e) times (c-component of the charge flux in franklins/cm$^2$ sec.).

tions. The vector potential (2), in addition to satisfying the inhomogeneous wave equation (6), has a four-dimensional divergence which vanishes:

$$\left( \frac{\partial}{\partial x^\mu} \right) A^{(b)}_\mu (x) = \epsilon_0 \int_{-\infty}^{+\infty} \delta'(x_\mu x_\nu) 2 x_\mu b_\nu d\beta = 0.$$  

(9)

We differentiate this zero divergence with respect to \( x^\mu \) and subtract from it (7), obtaining the field equations equivalent to the usual relations \( \text{div} E = 4\pi j \) and \( \text{curl} H = \frac{\partial E}{\partial t} - \frac{4\pi j}{c} \).

The other pair of Maxwell's equations follow identically from the definition (4) of the \( F \) 's in terms of the \( A \) 's.

The fields (2) are distinguished from all other solutions of Maxwell's equations by being half the sum of the advanced and retarded Liénard-Wiechert potentials of particle \( b \):

$$A^{(b)}_\mu (x) = \epsilon_0 \int \frac{db_\mu}{d(\text{proper cotime})} \delta(x_\mu x_\nu) d(x_\mu x_\nu).$$  

(10)

Here, for example, \( R \) represents the retarded potential evaluated at that point on the world line of \( b \) which intercepts the light cone drawn from the point of observation into the past:

$$R^{(b)}_\mu (x) = \epsilon_0 \frac{1}{c} b_\mu x^\nu + \epsilon_0 \frac{1}{c} b^\nu x_\mu,$$  

(11)

and \( S \) similarly represents the advanced potential.

By way of illustration of these results in familiar cases consider first the case of a point charge, \( b \), at rest at the origin. Then retarded and advanced fields are identical, all components of the four-potential vanish except the last, \( b^4 = \frac{1}{c} \frac{\partial (\text{proper cotime})}{\partial t} = 1 \), \( x_4 = t^4 - x^4 = x^4 - b^4 = \text{elapsed cotime} - \text{distance to point of observation} = r \), and the scalar potential has the familiar value \( \epsilon_0/r \). Next, in the case of a slowly moving point charge, it similarly follows that \( A^m = \epsilon_0 (b^m/c)^{2r}/c^2 \). If this point charge is at the same time being accelerated, then the derived electric field has at large distances the value \( E = -\epsilon_0 (b^m/c)^{2r}/c^2 \). where \( b_4 \) is the component of the three-vector \( b \) perpendicular to the line \( r \). This result refers only to the field of the particle in question. In the idealized case of a universe containing charged particles sufficient in number to absorb all electromagnetic disturbances, the advanced fields of the particles of the absorber will combine with the given field to produce the full retarded field of experience, \( -\epsilon_0 (b^m/c)^{2r}/c^2 \), as shown in III.

As a final example consider a fixed linear conductor past any point of which flow per second \( i/e \) particles of charge \( e \). The interval of cotime between the \( k \)th and the \((k+1)\)st particle is \( ce/i \). The coordinates of the \( k \)th particle are

$$k^m(\gamma) = s^m(\gamma) \quad (m=1, 2, 3)$$

$$k^4(\gamma) = s^4(\gamma) + kce/i \quad (k=-\infty, \cdots, -1, 0, 1, \cdots)$$  

(14)

where \( s^m(\gamma) \) is the parametric representation of the curve of the wire. The four-potential at a point of observation an appreciable distance from the wire is obtained by summing over all the particles or equivalently, because of the close spacing of the charges, by integrating over \( k \):

$$A^m(x) = \epsilon_0 \int \int \left[ \delta(r(\gamma)) - (c - s^4(\gamma) - kce/i)^2 \right]$$

$$\times d\gamma \frac{ds^m(\gamma)}{d\gamma} d\gamma = \left\{ \begin{array}{ll}
 i \int ds^m(\gamma)/cr(\gamma) & \text{for } m = 1, 2, 3 \\
 \epsilon_0 \int dk/r & \text{for } m = 4.
\end{array} \right.$$  

(15)

Here \( r(\gamma) \) is the magnitude of the vector \( x(\gamma), y(\gamma), z(\gamma) \) which runs from the point \( \gamma \) of the curve to the point of observation. The scalar potential of Eq. (15) will normally be compensated wholly or in part by contributions from opposite charges at rest and need not be considered here. From the vector potential follows an expression for the magnetic field

$$H = \text{curl} A = i \int (ds \times r)/cr^3,$$  

(16)

identical with that due to Ampère.

To go further in deriving well known results would be pointless. Adequate textbooks exist. They treat well defined problems of electromagnetism, where there is no compelling reason to consider a particle to act on itself. Thus all their analyses are immediately translatable into terms of the present modified or *adjunct field theory*. However, this point of view is mathematically identical with that of action at a distance. Consequently the theory of direct interparticle action, far from attempting to replace field theory, joins with field theory to provide the science of electromagnetism with additional techniques of mathematical analysis and to facilitate deeper physical insight. The rest of this article may illustrate how the two points of view join hands to elucidate in four-dimensional mechanics the principle of action and reaction and the laws of conservation of momentum and energy.

**ACTION AND REACTION**

Laws of conservation of angular momentum, energy and linear momentum are well known to exist in any
theory for which the equations of motion are derivable from an action principle which is invariant with respect to rotation, translation, or displacement of the time coordinate.\textsuperscript{15} Thus Fokker\textsuperscript{16} has derived an energy-momentum conservation principle for an idealized situation in which there are only two particles, of which \(a\) acts on \(b\) via purely retarded forces. The present treatment is the natural generalization of Fokker's analysis to the case of a theory which is symmetric between every pair of particles and which is based on the action principle (1). It will be sufficient to prove the conservation law for a single pair of particles in order to see the corresponding result for a system of particles.

For the typical particle \(a\) let the four-vector of energy and comomentum be denoted by

\[
m_{a}c(1-\varphi/c^2)^{-1} = \begin{cases} G^1 = G_1 \\ G^2 = G_2 \\ G^3 = G_3 \\ G^4 = G_4 \end{cases}
\]

three space components of

\[
G^2 = G_2 = \text{kinetic comomentum (velocity of light times kinetic momentum: expressible in energy units).}
\]

Then the change in kinetic comomentum and energy in the interval of proper cotime, \(da\), on account of the action of particle \(b\) follows directly from the equations of motion (5) and the expressions (4) and (2) for the force coefficients:

\[
dG_m(a,b) = m_{a}c^{2} \frac{\partial a_{m}}{\partial a} da = e_{a} \epsilon_{a} da_{a}^{*} \times \left\{ \frac{(\partial/\partial a^{*})}{} \int_{a_{m}}{b_{m}} \frac{\delta(ab,ab^{*})}{db} \right\}. \tag{17}
\]

We carry out the differentiations with respect to the coordinates \(a\) and add to the result the following zero quantity

\[
e_{a} \epsilon_{a} da_{m} \int_{-\infty}^{\infty} {\delta(ab,ab^{*})} db, \tag{18}
\]

thus finding for the impulse

\[
dG_m^{(a)}(a,b) = 2e_{a} \epsilon_{a} \int_{b_{m}}^{b_{\infty}} {\delta(ab,ab^{*})} \times \left( ab_{a}da^{*}db_{a} - db_{a}da^{*}ab_{a} - da_{m}db^{*}ab_{m} \right). \tag{19}
\]

In this expression the integrand is changed in sign but unaltered in value by an interchange of the roles of particles \(a\) and \(b\).

To the result just obtained we give the following obvious interpretation:

(1) The right hand side of (19), after removal of the integral sign, represents in terms of the symbolic delta-function the transfer of impulse or energy to \(a\) during the stretch of cotime \(da\) from effects which originate at \(b\) in the cotime interval \(db\).

(2) There is no energy or impulse transfer except when the stretch \(db\) of the world line of \(b\) is intersected by either the forward or backward light cone drawn from \(a\), i.e., \(b\) acts on \(a\) through both retarded and advanced forces.

(3) The impulse communicated to \(a\) over the portion \(da\) of its world line via retarded forces, for example, from the stretch \(db\) of the world line of \(b\) is equal in magnitude and opposite in sign to the impulse transfer from \(a\) to \(b\) via advanced forces over the same world line intervals (equality of action and reaction).

The relativistic generalization of the Newtonian principle of action and reaction as just stated is obviously not identical with the non-relativistic formulation. In no Lorentz frame of reference are action and reaction simultaneous. For the instant at which \(a\) experiences a force from \(b\) there is not one corresponding time at which \(b\) gets a back reaction, but two instants.\textsuperscript{17} Thus for a given point on the world line of \(a\) we can make two statements about the transfer of energy (or impulse) from \(b\). Each statement refers to a single one of the two parts of the total transfer. It is evidently reasonable that the law of action and reaction should have this Jacob's ladder character in 4-dimensional space-time.

### ENERGY AND MOMENTUM OF INTERACTION

Considering two isolated particles \(a\) and \(b\), we immediately conclude from the law of action and reaction as just stated the constancy in time of the total energy and comomentum four-vector

\[
G_m(a,b) = m_{a}c^{2} \delta_{m}(a) + m_{b}c^{2} \delta_{m}(b) + \frac{2e_{a} \epsilon_{a} \int_{b_{m}}^{b_{\infty}} {\delta(ab,ab^{*})} \times \left( ab_{a}da^{*}db_{a} - db_{a}da^{*}ab_{a} - da_{m}db^{*}ab_{m} \right)}{(\text{constant})}. \tag{20}
\]

In the case of more particles we have a corresponding expression with a kinetic term for each individual particle and an interaction term for each pair of charges. Thus \(G_m\) becomes a function of as many parameters \(a, b, c, \ldots\) as there are particles. To prove constancy with respect to a given parameter, such as \(a\), we have only to differentiate (20) and insert for \(m_{a}c^{2}\delta_{m}(a)\) the quotient \(dG_m(a)/da\) obtained from (19).

Evidently we have in (20) what may be called a many-time formulation of the conservation laws, derived of course from the equations of motion, but from which conversely the equations of motion are derivable with equal ease.

The interpretation of the double integral in (20) as an interaction energy is obvious in the case of two stationary charges separated by a distance \(R\). Thus by integration we find for \(G^2\) the familiar result \(m_{e}c^{2} + m_{e}c^{2} + e_{e}e_{e}/R\).

\textsuperscript{16} A. D. Fokker, Zeits. f. Physik 88, 386 (1929).

\textsuperscript{17} L. Page, Am. J. Phys. 13, 141 (1945), has reviewed the complications which come from comparing action and reaction at the same time.
In the case of individual moving charges it is sometimes convenient to add to the idea of kinetic comomentum and energy $G_m^{(a)}$ the notion of potential comomentum and energy

$$U_m^{(a)} = e_a \sum_b A_m^{(b)}(a\alpha), \quad (21)$$

and total comomentum and energy,

$$P_m^{(a)} = G_m^{(a)} + U_m^{(a)}, \quad (22)$$

In terms of these expressions, the four-vector of energy and comomentum of the whole system takes the form

$$G_m(\alpha, \beta, \cdots) = \sum_a P_m^{(a)}(\alpha) + \sum_{\alpha < \delta} 2e_a e_b$$

\[ \times \left( \int_a^\beta \int_{-a}^{\beta} - \int_a^\beta \int_{-a}^{\beta} \right) b'(ab,ab')ab_m da^4 db. \quad (23) \]

The summation of the potential energies so to speak counts twice the interaction between each pair of particles. The double integrals in (23) correct for this overcount.

From either Eq. (20) or Eq. (23) for the energy of the system it is clear (see Fig. 3) that the electromagnetic energy of a finite number of particles is definable from a knowledge of only a finite stretch of their world lines. It is also evident that particles which come together in otherwise charge free space, interact, and then separate in a regular way, will in the end experience no net loss of energy to outer space. Both features of the four-vector $G_m$ are reasonable in the mathematical description of a physically closed system.

**RELATION OF INTERACTION ENERGY TO FIELD ENERGY**

In field theory it is customary to attempt to define throughout space a symmetrical stress energy tensor\(^{18}\)

$$T_{mn}(x)$$

with the following properties:

1. The divergence $\partial T_{mn}/\partial x^s$ vanishes at every place where there is no particle.
2. At the location of a typical charge $a$ this divergence becomes singular in such a way that its integral over a small volume element containing the charge gives the value of the electromagnetic force acting on that charge:

$$-\delta a \int \int (\partial T_{mn}/\partial x^s) dx^s dx^3 = m_a c^2 \delta_{in}$$

\( \text{neighborhood of a} \quad (24) \)

when the integration extends over a region of constant time which contains $a$. When the integration proceeds over an arbitrary space-like region or "surface," $\sigma$, such that there is no pair of points in

\( T_{11}, \text{ force in positive } x\text{-direction across unit area in } xy \text{ plane exerted upon medium on negative side of plane by medium on positive side (equal in the Maxwell theory to } (8x)^{-1} \times (E^2 + H^2 + E_0^2 + H_0^2). \)

\( T_{16}, \text{ velocity of light times energy flux in } x \text{ direction per cm}^2 \text{ of } xy \text{ plane and per sec. (Maxwell value } (4x)^{-1}(E_0H - E_HH_0) \times (E^2 + H^2). \)

\( T_{44}, \text{ negative of the energy density (usual expression } - (8x)^{-1} \times (E^2 + H^2). \)

\(^{18}\) Typical components are

\[ T_{uu} = \int \int (\partial T_{uu}/\partial x^s) dx^s dx^3 = m_a c^2 \delta_{iu} \]

\( \text{neighborhood of } a \quad (24) \)

Here, the surface can be connected by a light ray, then the corresponding statement is

$$m_a c^2 \delta_{in} - \delta a \int \int (\partial T_{uu}/\partial x^s) dx^s = 0. \quad (25)$$

\( \text{neighborhood of a} \)

For every space-like surface $\sigma$ there is defined a *four-vector of energy and comomentum*

$$G_m(\sigma) = \sum_a m_a c^2 \delta_{in} + \delta a \int \int T_{mn} da^m, \quad (26)$$

which is conserved in the sense that its value is completely independent of the choice of $\sigma$. Thus consider a change $\delta \sigma$ in the surface $\sigma$—i.e., an alteration from $x^a(u, v, w)$ to $x^a + \delta x^a(u, v, w)$ and the associated alterations $da, db, \cdots$ in the points where the respective world lines intersect this surface. Then the change in $G_m$ is expressible via the theorem of Gauss in terms of an integral over the volume, $\omega$, comprised between the two surfaces:

$$\delta G_m = \sum_a m_a c^2 \delta_{in} da^a + \delta a \int \int \int (\partial T_{mn}/\partial x^a) da^m. \quad (27)$$

But the integrand vanishes everywhere except in the immediate neighborhood of the typical particle, $a$, and there—writing $da^m = da da^a$, and using (25)—we conclude that the contribution from the integral just cancels out the first term in $\delta G_m$.

Is there any choice of the tensor $T_{mn}$ in the adjunct field theory which will yield for the energy-comomentum vector $G_m(\sigma)$ of (26) a value identical with the corresponding vector $G_m(\alpha, \beta, \cdots)$ of the theory of direct interparticle action? The appropriate tensor may be constructed when one recalls that the field of a given particle is to produce changes only in the motions of the other particles, and that the principle of action and reaction connects the retarded effects exerted for example by $a$ on $b$ via the retarded field $(1/2)R_{mn}(a)$ with the advanced effects exerted by $b$ on $a$ via the advanced field $(1/2)S_{mn}(a)$:

$$T_{mn}(x) = \sum_{a \neq b} (R^{(a)}(x) \& S^{(b)}(x))_{mn}. \quad (28)$$
Here $R$ and $S$ denote the retarded and advanced Liénard-Wiechert fields, so that $F_{mn} = (1 / 2) R_{mn} + (1 / 2) S_{mn}$. For a convenient abbreviation we have adopted the notation
\[
(R + S)_{mn} = \left( R_{m} = S_{m} + S_{m} = R_{m} + \frac{1}{2} g_{mn} R_{\mu \nu} S^{\mu \nu} / 8 \pi \right) \quad (29)
\]
with $g_{mn} = 0$ for $m \neq n$ and $g_{12} = g_{13} = g_{23} = 1 = -g_{11}$.

That the tensor $T_{mn}$ of (28) does lead to the energy-momentum four-vector (20) of the theory of action at a distance is proven in the appendix. Here we shall only establish that the stress energy tensor satisfies the conditions (1) and (2) (and hence (3)). Thus, we evaluate the divergence of the typical term in the stress-energy tensor of Eq. (28), finding
\[
\delta T_{mn} / \delta x_{m} = \sum_{a \neq b} \{ (S^{(b)}) / 16 \pi \} (\partial R_{mn}^{(a)} / \partial x^{n})
\]
\[
+ \partial R_{mn}^{(a)} / \partial x^{m} + \partial R_{mn}^{(a)} / \partial x^{n}
\]
\[
+ (S_{mn} / 8 \pi) (\partial R_{mn}^{(b)} / \partial x_{n})
\]
\[
+ \text{similar term with } S^{(b)} \text{ and } R^{(a)} \text{ interchanged}. \quad (30)
\]

Here the first three cyclically related terms cancel, as seen for example from the antisymmetric representation of the fields via potentials; and the divergence of $R$ gives the same charge and current distribution (8) which appeared in the time-symmetric case. Using this circumstance, and combining terms, we have
\[
\partial T_{mn} / \partial x_{m} = \sum_{b \neq a} F_{mn}^{(b)}(x) j^{(b)}(x)
\]
\[
= \sum_{b \neq a} F_{mn}^{(b)}(x) e_{a} \int (x^{1} - a^{1}) (x^{2} - a^{2})
\]
\[
\times \delta (x^{3} - a^{3}) \delta (x^{4} - a^{4}) d^{4} \alpha d \alpha
\]
\[
= \sum_{b} \int (x^{1} - a^{1}) (x^{2} - a^{2}) (x^{3} - a^{3})
\]
\[
\times \delta (x^{4} - a^{4}) m_{ab} \delta \omega_{a} d \alpha, \quad (31)
\]
in complete satisfaction of requirements (1) and (2).

As alternative choice for the stress energy tensor which also has the properties (1), (2) and (3) is that proposed by Frenkel, who was among the first to stress the notion of fields as always adjunct to specific particles:
\[
T_{mn}^{*}(x) = \sum_{a \neq b} (F^{(a)}(x) \& F^{(b)}(x))_{mn}. \quad (32)
\]

Thus the difference between Frenkel's tensor and the canonical tensor (28) is a quantity
\[
T_{mn}^{*} - T_{mn} = \sum_{a \neq b} \{ (3 / 2) R^{(a)} - \frac{1}{2} S^{(a)} \} \& \{ (3 / 2) R^{(b)} - \frac{1}{2} S^{(b)} \} \quad (33)
\]
which has everywhere a zero divergence.

The possibility of more than one expression for the stress-energy tensor with the same divergence is well known in the usual single-field formulation of electrodynamics, and is not surprising here. However, the expressions for field energy also turn out to differ (Table I).

The energy-momentum four-vector $G_{mn}$ defined by (26) and (28), and the alternative four-vector $G_{mn}^{*}$ defined by (26) and (32), are both ordinarily finite for a system of point charges. In illustration, note that near a typical particle $a$ the corresponding field varies as $1 / r^{2}$, the field of any other particle $b$ is finite, the volume element is proportional to $4 \pi r^{2} d r$ and the integral of (26) converges, yielding for example in the interaction energy $e_{a} \delta_{a b} / r_{a b}$ for two stationary point charges separated by the distance $r_{a b}$. The density of field energy, while finite, is not positive definite, even for two particles of the same charge. Also the flow of energy and momentum may have finite values at a point in space where the total field, $F^{(a)} + F^{(b)} + \cdots$, actually vanishes. This result, unexpected from the point of view of the usual field theory, nevertheless presents no logical difficulties.

**ENERGY OF RADIATION**

The canonical and the Frenkel tensors, which give the same interaction energy in the case of two charges which are at rest, give different results for the case of a

single accelerated particle in a completely absorbing universe. There we have in the neighborhood of the radiating source $F^{(a)} = (1/2)R^{(a)} + (1/2)S^{(a)}$ and $F^{(b)} + F^{(c)} + \ldots = (\text{sum of advanced fields of absorber particles})^{22} = (1/2)R^{(a)} - (1/2)S^{(a)}$. For the parts of these fields which are proportional to the acceleration of the charge, and which vary at large distance as $1/r$, we have for $R^{(a)}$ and $S^{(a)}$ respectively a zero value except for an instant $r/c$ seconds after or before the moment of acceleration. The corresponding energy flux (Table II) satisfies in both the Frenkel and the canonical formulations the law of conservation of energy, but agrees only in the canonical case with customary ideas of energy localization. From the standpoint of pure electrodynamics it is not possible to choose between the two tensors. The difference is of course significant for the general theory of relativity, where energy has associated with it a gravitational mass. So far we have not attempted to discriminate between the two possibilities by way of this higher standard.

**CONCLUSION**

We conclude that the theory of direct interparticle action, and the equivalent adjunct field theory, provide a physically reasonable and experimentally satisfactory account of the classical mechanical behavior of a system of point charges in electromagnetic interaction with one another, free of the ambiguities associated with the idea of a particle acting upon itself.

**APPENDIX**

To express the integral of the field energy which appears in (26), we express each field as a superposition of elementary fields from each infinitesimal range of path $dx$, and the tensor $T_{mn}$ or $T_{ab}$ as the superposition of parts due to stretches $dx$ of the world line of $a$ and $b$ of $b$. We use the notation $T^a_{\alpha\beta}(\dot{x})$, etc. Thus the four-potential $(\partial R^{(a)})/ax$ arises from a charge which appears for an instant at $(\partial R^{(a)})/ax$ and disappears at $(\partial R^{(a)})/ax + (\partial R^{(a)})/ax$.

The lack of conservation of the charge which generates the elementary potential causes the four-divergence of $\partial R^{(a)}/ax$ to equal a non-zero scalar, $\gamma$,

$$\gamma = \gamma^{(a)}(x, \alpha) = \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

$$= \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

This integral however satisfies the conservation condition $\int \delta^{(a)}(x, \alpha) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right) = 0$. This circumstance permits some latitude in the definition of the elementary field in terms of the potential. It will prove useful to adopt the definition

$$R_{(a)}^{(a)} = \frac{\partial R^{(a)}}{\partial x} \left( \frac{\partial x}{\partial a} \right)$$

The elementary component of the stress-energy tensor is not symmetric in its two indices, but its divergence is found by direct algebra to have the simple value

$$\left( \frac{\partial R^{(a)}}{\partial x} \right) \left( \frac{\partial x}{\partial a} \right) = \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

$$= \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

$$= \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

We integrate (36) over a four-dimensional region of the form shown in Fig. 4. Of the terms on the right the second vanishes throughout this region, and the first gives

$$\frac{1}{2} R_{(a)}^{(a)} = \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

$$= \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

$$= \frac{1}{4} \int \left( \delta^{(a)}(x, \alpha) \right) \left( \delta^{(a)}(x, \alpha) \right) \left( \frac{\partial^{(a)}}{\partial x} \right) \left( \delta^{(a)}(x, \alpha) \right)$$

when $b > a$, and zero otherwise. The four-integral on the left hand side may be expressed via the theorem of the Gauss in the form

$$\int \left( \frac{\partial R^{(a)}}{\partial x} \right) \left( \frac{\partial x}{\partial a} \right)$$

Here the integral, which goes over the whole of the three-dimensional region or "surface" in the figure, contributes only over the upper region because of the vanishing elsewhere of at least one of the fields in question. The elementary contributions just computed we now sum over the world line of a from $-\infty$ to a and over the world line of $b$ from $\beta$ to $\infty$, where $a$ and $b$ determine the points where the world lines of $a$ and $b$ intersect the space-like surface $s$. We have then only to erase the dagger in (39). The converse expression, with $R^{(a)}$ and $R^{(b)}$, we obtain by interchanging the roles of $b$ and $a$ in (38) and in the limits of integration. This way follows at once the identity of expression (20) for the energy in the theory of direct interparticle interaction and the canonical expression (26–28) of the adjunct field theory.

When instead the Frenkel expression (32) is used for the stress-energy tensor, then there results an increment in the energy-comomentum four-vector given by the expression

$$G_{\alpha}^{(a)}(\alpha, \beta) = \frac{1}{2} R_{\alpha}^{(a)} \int_{-\infty}^{\infty} (ab) \frac{d\theta}{d\alpha}$$

$$= \frac{1}{2} R_{\alpha}^{(a)} \int_{-\infty}^{\infty} (ab) \frac{d\theta}{d\alpha}$$

a covariant which is independent of $\alpha$ and $\beta$ and which has an interesting relation to the two world lines in question.
