combined ether extracts were washed with concentrated sodium chloride solution and dried over magnesium sulfate. Evaporation of the ether gave a brownish crystalline mass. Recrystallization from hot water gave thin white plates, mp 119-120'; yield 40%. From hot water gave thin white plates, mp 119-120'; yield 40%.

J. Amer.

was converted to the ethyl ester in anhydrous ethanol with hydrochloric acid gas as catalyst. Recrystallization from toluene gave thin white plates, mp 119-120'; yield 40%; ir 3350, 1370 (OH), 1610, 1525, 1450 (aromatic ring), 1700, 1200 (ester) cm⁻¹; nmr 3.10 (s), 3.35 (m), 4.14 (s), 5.85 (qu), 7.25 (m), and 8.78 ppm (d).  

**Oxidation of Hydroquinone Acids and Esters. General Method**—The same general method was used as already reported, using ferric chloride as oxidizing agent in an ethanol-water mixture.

1,4-Benzquinone-2,5-bis(3'-propanoic acid).—Recrystallization from tetrahydrofuran by addition of heptane gave yellow needles, mp 191-193°; yield 86%; ir 1710, 1228 (COOH), 1635, 1620 (quinone) cm⁻¹.  

1,4-Benzquinone-2-(3'-propanoic acid) was obtained as small, dark yellow needles from hexane-tetrahydrofuran, mp 137-139°; yield 72%; ir 1710, 1210 (COOH), 1660, 1598 (quinone) cm⁻¹.  

2-(2'-Carboxethoxy)-1,4-benzquinone was obtained as a bright yellow oil which crystallized on cooling with a Dry Ice-acetone mixture as long yellow needles, mp 11-15°; yield ca. 85%; ir 1730, 1235 (COOH), 1660, 1600 (quinone) cm⁻¹; nmr 3.23 (m), 3.82 (qu), 7.3 (m), and 8.74 ppm (d).  

1',2'-Bis(2,5-dimethoxyphenyl)ethane (VI), 1,4-Dimethoxy-2-chloromethylbenzene (27.7 g (0.15 mol)) was dissolved in 120 ml of tetrahydrofuran. This solution was slowly added to a mixture of 1.92 g of magnesium turnings and 40 ml of tetrahydrofuran under vigorous stirring, the usual precautions for the preparation of Grignard compounds being taken. After the addition was finished, the reaction mixture was refluxed for 4 hr, tetrahydrofuran was distilled off, and the residue was heated to 100° for 2 hr on a steam bath. The reaction mixture was then acidified with 6 N hydrochloric acid and extracted with ether. Evaporation of the ether gave a slightly yellow oil which soon crystallized. Recrystallization from methanol gave white needles, mp 72°; yield 86%; nmr 3.29 (6), 5.29 (6), 5.35 (q), and 7.4 ppm (d).  

1',2'-Bis(2,5-dihydroxyphenyl)ethane (I).—Compound VI, 8.0 g, was refluxed for 4 hr with 75 ml of 48% hydrobromic acid. From the filtered reaction mixture, dark brown crystals separated on cooling. Recrystallization from a large amount of boiling water gave white needles (4.0 g) which were further purified by sublimation at 200° (0.3 mm) bath temperature. They melted at 225° with decomposition. The same compound was simultaneously prepared by Manecke and Zerpner, 13 ir 3120, 1375, 1196 (OH), 1620, 1570, 1455 (aromatic ring) cm⁻¹.  

1',2'-Bis(2,5-benzquinonyl)ethane (III).—Compound I, 1.2 g, in 50 ml of tetrahydrofuran was oxidized by stirring for 30 min with 5 g of silver oxide and 5 g of magnesium sulfate. The mixture was filtered rapidly, and the solvent was removed in vacuo. The dark brown residue, 1.0 g, was purified by sublimation at 180° (0.3 mm) bath temperature to yield microscopic yellow crystals, mp 194°; ir 1660, 1603 (quinone) cm⁻¹.

**Nuclear Magnetic Resonance Spectroscopy. Proton Spectra of Diallylmercury**

HERMAN E. ZIEGERT AND JOHN D. ROBERTS

Gates and Crellin Laboratories of Chemistry, California Institute of Technology, Pasadena, California 91109

Received March 8, 1969

Changes have been observed in the nmr spectra of diallylmercury as a function of temperature which seem explicable in terms of allylic rearrangement and intramolecular exchange. Analysis of the proton spectra of diallylmercury spectra using a modified LAOCOON computer program gave coupling constant and chemical shift parameters which reproduced the spectra at 60, 100, and 220 MHz.

Analyses of the nmr spectra of three dipropenylmercury compounds have been reported with the objective of establishing their configurations and the stereochemistry of their preparation from propenyllithiums. Similar studies of diallylmagnesium (diallylmercury) do not appear to have been published, although it offers the additional possibility of undergoing both intramolecular and intramolecular exchange which, in principle at least, are distinguishable by nmr. Diallylmercury is expected to have a carbon–metal bond intermediate in ionic character between tetraallyl and diallyllead, which have been found to exhibit ABCD₄ and AB₄ nmr spectra, respectively. The AB₄ spectra observed for allylmagnesium bromide and diallylmagnesium have been interpreted as indicating a rapid allylic rearrangement (either inter- or intramolecular) between the possible allylic isomers.

It was of particular interest to investigate variations in the nmr spectra of diallylmercury with temperature to see whether rearrangement could be detected and whether or not such rearrangement occurs by intramolecular group exchange and can be distinguished from intramolecular rearrangement by disappearance or retention of the ¹⁹Hg satellite lines in the progression of cooling. Emerson, and Z. Oliver, Inorg. Chem., 2, 1261 (1963).  

However, see references in P. West, J. T. Purnott, and S. V. McKinley, J. Amer. Chem. Soc., 90, 797 (1968), to unpublished work of P. West in which conclusions similar to those of this paper were reached.

of formation of an AB₄-type spectrum from an ABCD₂ spectrum.

As a prelude to this, analyses were carried out of the 60-MHz and 100-MHz diallylmercury spectra with the aid of a modified LAOCOON II computer program. The coupling constant and chemical shift parameters so obtained were then checked with 220-MHz spectra.

**Results**

The 60-MHz spectrum of neat diallylmercury (Figure 1) shows relatively broad, poorly resolved lines which result from a superposition of spectra of the ABCD₂ and ABCD₂X types. Upon cooling, the spectral lines sharpen noticeably. The same behavior results on dissolution in solvents such as tetrahydrofuran (Figure 1) or carbon tetrachloride. A combination of dilution and cooling was found to provide the maximum achievable resolution. Considerable line broadening was observed on heating in tetrahydrofuran (Figure 1), but even at 108°C, the highest temperature attempted, the spectra were essentially of the ABCD₂ type and it appeared unlikely that AB₄ (and possibly AB₄X) spectra could be observed at any reasonable temperature for tetrahydrofuran solutions.

These observations, although far from clean-cut, may be interpreted in terms of concomitant allylic rearrangement and intermolecular exchange. The argument for intermolecular exchange is that degradation of the ABCD₂X spectrum in the direction of an ABCD₂ spectrum seems qualitatively faster than the degradation of the ABCD₂ spectrum in the direction of an AB₄ spectra. Exclusive intramolecular rearrangement would be expected to lead to AB₄ spectra with mercury satellites and probably would be less dependent on concentration than is in fact observed.

The nmr spectra of diallylmercury were analyzed by essentially conventional techniques. Chemical shifts and coupling constants estimated by first-order approximation from 60-MHz and 100-MHz spectra provided trial spectral-line positions for use in the iterative LAOCOON II program. The parameters so obtained are given in Table I with the nuclei numbered as in 1. The theoretical spectrum corresponding to these parameters gave an acceptable match to the experimental spectrum (Figure 2). The agreement between the parameters obtained for 60, 100, and 220 MHz is quite satisfactory.

The small variations of some of the coupling constants (Table I) observed on cooling diallylmercury in tetrahydrofuran solution could be caused by small changes in the populations of various conformational isomers.

**Experimental Section**

Diallylmercury (mp -41 to -40°C) was prepared from allylmagnesium bromide, following the literature. The sample used for the spectral analysis was dissolved 1:4 (v/v) in perdeuteriotetrahydrofuran and sealed under pre-purified nitrogen in a thick-wall, precision-bore tube. The 60-MHz spectra were obtained with a Varian Associates A-56/60-A spectrometer equipped with a modified V-6040 variable temperature controller at 39, 57, 63.5, 74, and 93°C, and calibrated with a Heiselett-
The simplification of the H-1 multiplet to a symmetrical quartet (B) using the chemical shift and coupling parameters for the Varian Associates HA-100 spectrometer operated in the freoin perdeuteriotetrahydrofuran at 60 MHz and calculated 60-MHz analysis as listed in Table I.

**Bromine Addition to Olefins in Aqueous Solution**

DIPAK ACHARYA AND MIHIR NATH DAS

Physical Chemistry Laboratories, Jadavpur University, Calcutta-32, India

Received September 18, 1967

Rates of addition of bromine to methyl acrylate, methyl crotonate, methyl methacrylate, and acrylamide in aqueous solutions have been measured electrometrically in the presence of added bromide at 20, 30, and 40°. The rate constants for addition of bromine to some more olefins in aqueous solution in the presence of added bromide at 20, 30, and 40°. The results are not strictly in conformity with what should be expected from structural considerations.

Rates of addition of bromine to several olefins in aqueous solutions were measured by Kanyaev and he concluded that the relative reactivity of molecular bromine and tribromide ion varies continuously with the reactivity of the olefin and also that the proportion of the dibromide in the product is equal to the fraction of reaction effected by tribromide ion. No support for this view has been provided by the studies of Atkinson and Bell. From their kinetic results, coupled with product analysis, Atkinson and Bell postulated a general mechanism which is consistent with their findings. More recently Bell and Pring have reported the kinetic results for addition of bromine to some more olefins in aqueous solution in the presence of added chloride and bromide, which tend to substantiate their earlier conclusions. In general, the velocity constants for reaction with bromine or tribromide ion, varying over eleven powers of ten, show an approximate correlation with the Taft substituent constants.

The object of the present investigations was to determine the activation energy and the entropy of activation for the reaction with bromine as well as
