Canonical analysis of a recently proposed [1] linear+quadratic curvature gravity model in $D = 3$
establishes its pure, irreducibly fourth derivative, quadratic curvature limit as both ghost-free and
power-counting UV finite, thereby maximally violating standard folklore. This limit is representative
of a generic class whose kinetic terms are conformally invariant in any dimension, but it is unique in
simultaneously avoiding the transverse-traceless graviton ghosts plaguing $D > 3$ quadratic actions
as well as double pole propagators in its other variables. While the two-term model is also unitary,
it additional mode’s second derivative nature forfeits finiteness.

It is a truism of Lorentz-invariant local field theory that fourth (or higher) derivative actions entail ghosts: Any
Lagrangian of the form $L = XO(M)O(m)X$, with $O(m)$ a (tensorial) Klein-Gordon operator of mass $m$ (possibly
0), and $X$ a (tensorial) field, has ghost propagator $P^{-1} \approx 1/O(M) - 1/O(m)$. Of the apparent exceptions,
Gauss-Bonnet-Lovelock gravity and scalar ”Galileons” [2]
have neither kinetic terms nor higher derivatives. Pure scalar curvature, $L = R + R^2$ models, do have higher
derivatives at metric level, but are merely second-order
in their proper, scalar-tensor, incarnations, a point whose
analog we shall encounter here. Quadratic curvature
models with torsion, but with affinities as independent
variables, are thereby not strictly higher order. We also
exclude prescriptions that simply ”improve” the signs of
ghost poles by fiat.

For background, ghosts–excitations with negative
probability (in quantum language), are unacceptable
physically, as their existence destabilizes a system, much
as do their classical counterparts, negative energy excitations,
by destroying the ground state. Historically, they
have nevertheless continued to exert interest in quantum
field theory: Fourth order kinetic energies mitigate the
ultraviolet catastrophes of loop corrections, most notably
in $D = 4$ General Relativity [3] whose coupling constant
has inverse length dimensions, requiring an infinite number
of additional terms that destroy its predictive power.
I emphasize that the present $D = 3$ toy model does NOT
( the “alas” in the title) indicate how to get physical
relied for real, $D = 4$ gravity: its very modest point is that
even the venerable linkage between higher derivative ac-
tions and ghosts/negative energy modes is not airtight.

This folk theorem has remained unchallenged until a recent [1] ($D = 3$) linear plus quadratic curvature model
claimed, by first reparameterizing the two-term metric
action into a ”two-tensor” form, to really represent two
massive ghost-free spin-2 modes, governed by the, second
order, Fierz-Pauli action. One appealing way to moti-
vate this, at first sight unlikely, ghost-avoidance is as fol-
lows. If the second-order equation $O(m)X = 0$ permits
only a vacuum solution, then the corresponding $1/O(m)$
“propagator” does not propagate any excitations; then
the effective derivative order of $O(M)$ $[O(m)X] = 0$, or
$O(m)[O(M)X] = 0$, drops from 4 to 2. But the (linear-
ized in $h = g - \eta$) Einstein tensor $G(h) = O(0)h$, being
the full Riemann curvature in $D = 3$, is the perfect (and
unique, as we shall see) exemplar of this mechanism: its
vanishing implies flat space in (and only in) $D = 3$, where
its propagator is pole-free. Furthermore, the specific pro-
posed quadratic combination ensures that “$O(M)$” is the
correct, separately ghost-free, FP operator. The pure
quadratic case is more like $O(0)^2X = 0$, and as we shall
see, it is not amenable to the reparameterization of [1];
whether it is ghost-free therefore requires detailed, met-
ric, study. This is our main purpose: we will conclude
that our limiting model indeed violates the folk theo-
rem, a first for an intrinsically fourth derivative action.
It is perhaps worth emphasizing at the outset that no
miraculous derivative evaporation occurs: the field equa-
tions remain of fourth order, but two derivatives form
a (harmless) Laplacian rather than a d’Alembertian, by
the workings of $D = 3$ tensor dynamics.

The analysis will be performed entirely in metric terms,
in a linearized expansion about flat space, where the de-
gree of freedom content can be analyzed without the irre-
levant complications of nonlinearity. The parameterization
proposed in [1] is treated in the Appendix. [Separately,
it is an old story that any model involving polynomials in
curvature allows $(A)dS$, as well as flat, vacua even with-
out an explicit cosmological term (see, e.g., [4]): these
states, also treated in [1], are not relevant in the present
context.] The canonical decomposition, much simpler in
$D = 3$ than in $D = 4$, will be further simplified by use of
(linearized) gauge invariance. The Lagrangians of [1] are
a one-parameter class,

$$ I[h] = \int d^3 x L(h) $$

$$ = \int d^3 x \left\{ - \frac{1}{2} m^2 R + (G^\mu_\nu G_{\mu\nu} - 1/2(trG)^2) \right\}, $$

up to an overall, dimension $L^1$, gravitational constant
that is set to unity. Our main focus is on the special,
$m = 0$, limiting case. It is actually part of a class of

*Electronic address: deser@brandeis.edu
(pseudo)conformal-invariant actions whose linearizations are invariant in any $D$, while their full extensions scale as powers of the conformal factor. Its $D=4$ representative is just the familiar Weyl action, which scales as the zeroth power. These actions are

$$ I = \int d^Dx S_{\mu\nu}S_{\alpha\beta}(g^{\mu\rho}g^{\nu\beta} - g^{\mu\nu}g^{\alpha\beta})\sqrt{-g}. $$

$$ S_{\mu\nu} \equiv R_{\mu\nu} - 1/2(D-1)g_{\mu\nu}R $$

$S_{\mu\nu}$ is the Schouten tensor. Its curl, in $D=3$, is the familiar Cotton-Weyl tensor, initially introduced in $D=4$ Einstein gravity [5].

We decompose the metric deviation’s components $h_{\mu\nu}$ into their orthogonal parts, insert these into the curvature and form the various scalars in (1) to display the action in terms of the independent, gauge-invariant, metric variables, where its excitation content becomes manifest. Conventions are $e^{\alpha ij} = +1$, signature $(-+++)$; the Einstein tensor is defined by (5) below. The 2+1 decomposition of the (six) $h_{\mu\nu}$ is

$$ h_{ij} = (\partial_i h_j + \partial_j h_i) + e^{\mu\nu\rho}e^{\iota\kappa\lambda}\phi_{\mu\nu\iota\kappa\lambda}, $$

$$ h_{0i} = \eta_i + e^{i\jmath}\psi_j, \quad h_{00} = n; $$

subscripts on the (indexless) variables denote normalized spatial derivatives, $\partial_i/\sqrt{-\nabla^2}$, to keep standard dimensions for $h$ and $G$. This decomposition is just the degenerate limit of the usual orthogonal one of [5], valid in all $D > 3$,

$$ h_{ij} = h_{ij}^{TT} + (\partial_i h_j + \partial_j h_i) + e^{\mu\nu\rho}e^{\iota\kappa\lambda}\phi_{\mu\nu\iota\kappa\lambda}, $$

$$ h_{0i} = \eta_i + \partial_j \psi_j, \quad h_{00} = n; $$

(4)

where $\psi_{ij}$ is an antisymmetric tensor that reduces to a scalar in 2-space. The crucial difference between (3) and (4) is that the familiar transverse-traceless, $\partial_i h_{ij}^{TT} = 0 = h_{00}^{TT}$, “graviton” variable is identically zero in 2-space. This preserves the model from the ghosts in the term $L \sim h_{TT} \nabla^2 h^{TT}$ that plague quadratic actions in $D > 3$. The second, bigger, surprise that emerges below is that there at all exists a quadratic, 4th derivative covariant action whose (non-TT) variables avoid double poles!

Turning to our canonical analysis, gauge invariance of the action lets us set the three gauge parts $h_i$ and $\eta$ of the metric to zero by imposing the usual gauge choice $h_{ij\cdot} = 0 = h_0\iota\iota$. There remain only the three gauge-invariant components $(\phi, \psi, n)$ in (3). The Einstein tensor,

$$ G_{\mu\nu} = \frac{1}{2}g^{\alpha\beta}\epsilon^{\mu\lambda\sigma}\partial_\alpha \partial_\sigma h_{\nu\lambda}, $$

is easily verified to have the following 2+1 components,

$$ G_{00} = -\nabla^2 \phi, \quad 2G_{0i} = \sqrt{-\nabla^2} \phi_i + e^{\iota\jmath}(\nabla^2)\psi_{ij}, $$

$$ 2G_{ij} = \sqrt{-\nabla^2} \phi_{ij} + e^{\iota\jmath}(\nabla^2)\eta_{ij} + (e^{ik}\sqrt{-\nabla^2}\psi_{ij} + i \leftrightarrow j). $$

As a check, (6) manifestly obeys the Bianchi identity $G_{\mu\nu\cdot} = 0$. Orthogonality of the various $(h, G)$ components under integration then easily yields the canonical form of the action (1),

$$ I = \int d^3x \left( \frac{1}{2}\psi(-\nabla^2)(\Box - m^2)\psi + \frac{1}{2}m^2\phi(\Box - m^2)\phi 
+ \frac{1}{8}[\nabla^2 n - (\Box - 2m^2)\phi] \right). $$

(7)

Consider first the pure quadratic $m = 0$, fourth order, action. It is the sum of a (non-ghost: $-\nabla^2$ is positive) massless mode plus an irrelevant complete square: the no-go theorem is successfully violated! There is one non-dynamical relation, $\nabla^2 n - \Box \phi = 0$, between $\phi$ and $n$, due to the Weyl/conformal invariance exhibited in (2). In the two-term massive branch, the Einstein term not only adds a (correct sign) $m^2$ to the d’Alembertian acting on the vector, but the previous pure multiplier part is no longer a perfect square, restoration of which reveals an additional $\phi$-mode described by the second term in (7).

Unlike the first, vectorial one, it is a (spatial) massive tensor. It is worth noting that changing the relative coefficients in the quadratic combination (so losing its Weyl invariance), by adding $\delta L \approx R^2$ to (1) destroys the good properties of both branches, as one might expect from the preferred status of just this combination both as conformal invariant and as the special FP mass term respectively. To summarize, the $m = 0$, pure fourth order, conformally invariant limit of (1) indeed successfully breaks the no-go 4th derivative theorem. While its massive incarnation is likewise physical, as shown in the Appendix, this is because it is really a second-derivative two-field system, like the scalar-tensor form of $L = (R + R^2)$. Furthermore, the theory becomes power-counting finite: each higher loop adds a factor $\approx d^8kV^2P^3$, where $V \approx k^4$ and $P \approx k^{-4}$ are respectively the vertex and propagator. Hence there is a net gain of one power of $1/k$, overcoming the one-loop (formally cubic) divergence by (at latest) 5-loop order. [To avoid misunderstanding as to power counting, note that while one may remove two derivatives from the free action by a simple field redefinition that absorbs a factor $\sqrt{-\nabla^2}$ in each $\psi$, this would NOT change the net UV counting because each $\psi$ in the vertices would acquire the inverse of this factor.] Also, there are no conformal anomalies in odd $D$. However, given the theory’s special nature, perhaps not too much should be read into this first viable quantum gravity! In the above context, we resolve the seeming paradox that the $(m^2R + R^2)$ model seems to be both 4th, and (in its FP version) 2nd, order. The answer is clear from (7): Only the vector’s propagator behaves as $1/k^4$; the tensor’s just goes as $1/k^2$. Hence massive theory is nonrenormalizable, as expected also from the bad, $1/L$, dimension of its Einstein term.

Some final comments: (A) The, third derivative order, fermionic SUGRA extensions of the above tensor model are its vector-spinor companions: the $D = 3$ Rarita-Schwinger equation just states that the vector-spinor field strength $f^\alpha = \epsilon^{\alpha\beta\gamma}D_\alpha \psi_\beta$ vanishes; there are no excitations, so there is a priori hope of evading the
Their traceless parts \((f'_{\mu\nu}, G'_{\mu\nu})\) and their traces \((f, G)\),
\[
L(f, h) = -\frac{1}{4}m^2[f'_{\mu\nu} - 2m^{-2}G'_{\mu\nu}(h)]^2 \\
+ \frac{1}{6}m^2[f - \frac{1}{2}m^{-2}R^2] \\
- m^{-2}[G^2 - \frac{1}{2}G^2] - \frac{1}{2}hG(h),
\]
(A.2)
Dropping the irrelevant perfect squares, we recover (1), up to a trivial \(m^2\) rescaling. On the other hand, we may also combine the terms of (A.1) as
\[
L(f, h) = -\frac{1}{2}[(h-f)G(h-f)] + \frac{1}{2}\{fG(f) - \frac{1}{2}m^2(f'_{\mu\nu} - f^2)\},
\]
(A.3)
where \(G\) is the linearized Einstein operator (5). The first term is again irrelevant, stating that \(h-f = 0\) up to gauge, while the rest is just the standard pure Fierz-Pauli action for \(f\). However, the above procedures are valid only for \(m \neq 0\); equivalence is lost at \(m = 0\). Indeed, (A.1) states that both fields become trivial there: \(G(h) = 0 = G(f)\), whereas (7) displays a perfectly physical massless mode. An apparent way around this has been suggested in the second paper of [1], in terms of a different initial form, which seems to yield an effective, second-order, Maxwell action for the massless case. Unfortunately, that procedure involves insertion of on-shell information into the action (specifically inserting the solution of the linear Einstein equation-that its metric is pure gauge-into the remaining terms), which is of course not permitted. We conclude that the pure quadratic, \(m=0\), theory is irreducibly 4th order, without the 2nd order avatar underlying the massive case. Hence, as explained in text, only it is the novel exception.
