Nuclear Disintegration Energies^{*†‡}

D. M. VAN PATTTER,[§] *Physics Department, University of Minnesota, Minneapolis, Minnesota*

AND

WARD WHALING, *Kellogg Radiation Laboratory, California Institute of Technology, Pasadena, California*

I. INTRODUCTION

THIS compilation of nuclear reaction energies was undertaken to provide a systematic and comprehensive survey of the present state of our experimental knowledge of the energy released in nuclear reactions. Table I also affords convenient reference to the large number of experimental results scattered throughout the literature. Somewhat similar tables have appeared previously;^{1,2} in view of the rapid accumulation of new results, an up-to-date revision is felt to serve a useful purpose.

The Q values for the ground-state transitions are one source of information about the mass differences between the initial and final nuclei involved in the reaction. In the region of the light nuclei where the Q value measurements are sufficiently complete to relate all of the nuclei with $Z \leq 16$ to O^{16} by successive reactions, it is possible to determine the masses of the light nuclei from Q value measurements alone.³ For heavier nuclei the measurements are less abundant, and the results from nuclear spectroscopy must be used in conjunction with the information from mass spectroscopy and radio-frequency measurements. For both heavy and light nuclei, the most complete knowledge of nuclear masses will, of course, be achieved by combining the results from all of these different experimental techniques. Unfortunately, there are at present some discrepancies between the mass differences derived from nuclear reaction energies and those measured with the mass spectrograph. A first step toward the quantitative comparison, and eventual synthesis, of the results from

the different experimental methods is a separate compilation and examination of the results from each of the different methods. This table was prepared with this end in view. Beta-decay measurements are not included; these have been excluded not because of inconsistency with the measurements of nuclear reaction energies but because the number and complexity of the measurements of beta spectra suggest that they be treated in a separate report.⁴

II. ARRANGEMENT OF THE TABLE

In Column 1 are listed the reactions for which energy measurements have been made. The experimental values are listed in Column 2. An attempt has been made to include all of the measurements that have appeared in journals received in this country up to May, 1954. In a few instances early results have been omitted when they are known to involve considerable experimental error or when several more recent determinations of substantially higher precision have been reported. Some of the experimental values, designated by the superscript "a," do not appear explicitly in the reference cited and have been calculated by the present authors from experimental data given in the reference. A frequent example is a Q value calculated from the published reaction threshold energy by multiplying by the factor $M_0/(M_0+M_1)$, where M_0 is the atomic mass of the target nucleus and M_1 is the mass of the bombarding particle. When there is doubt that a reported Q value represents the ground-state transition, it has been enclosed in parentheses. It is quite possible that a few of the remaining Q values do not represent ground-state transitions, particularly in the region of the heavy nuclei where checks from reaction cycles are not available.

Column 3 indicates the method by which the measurement was made. A list of the abbreviations used to designate the experimental methods will be found at the end of Table I.

A great majority of the measurements of nuclear reaction energies are a comparison of the unknown energy with an established energy standard, and many measurements depend on an empirical range-energy relation. The energy standard employed, or reference to the range-energy relation used, is listed in Column 4. If separate energy standards were used for the bombard-

* Assisted by the joint program of the U. S. Office of Naval Research and the U. S. Atomic Energy Commission.

† Prepared at the suggestion of the Subcommittee on Nuclear Constants of the Committee on Nuclear Science of the National Research Council as part of a program on the compilation of experimental data relating to atomic masses. Subcommittee members: T. P. Kohman, chairman, W. Whaling, vice-chairman, H. E. Duckworth, L. G. Elliott, G. Friedlander, A. O. C. Nier, I. Perlman, W. H. Sullivan, and K. Way.

‡ Reprints of this article combined with others on nuclear constants published at the suggestion of the Subcommittee on Nuclear Science of the National Research Council may be obtained from the Publications Office, National Research Council, 2101 Constitution Avenue, Washington 25, D. C.

|| The masses used in these calculations are those given by K. T. Bainbridge in reference (2). If the mass M_0 is not known, the mass number has been used.

ing energy and the energy of the reaction products, both are listed. As the best values of these energy standards change with time, the results which depend on them must of course be altered also. Fortunately, recent changes in the commonly used energy standards have been small compared to other experimental uncertainty present in most measurements, and only a few results have had to be altered to establish conformity with the presently accepted values of the energy standards; any correction applied to such a measurement is explained in a footnote. Some of the (γ, n) threshold energies frequently employed as calibration points for betatron energy (e.g., the $\text{Cu}^{63}(\gamma, n)\text{Cu}^{62}$ threshold energy) are not yet well established. For these measurements the value assumed for the calibration energy is listed in Column 4, and no attempt has been made to correct such measurements to a common value of the calibration energy standard.

Column 5 gives a reference to the paper in which the measured value appears. When more than one measurement of a given reaction energy has been published by the same author or group of authors, the reference given refers to the latest published value. In the case where a correction has been reported in a later paper by another author, an additional reference with an asterisk has been added; for a subsequent revision of the error assigned to a measurement, the reference is designated with a double asterisk.

When several measurements of the same reaction have been reported by different authors, a weighted average value is listed in Column 6. The following procedure was used in calculating these weighted average values.

All published $\pm$ errors are treated as standard deviations. This assumption that all stated errors are of the same significance, regardless of the author's claim, is open to criticism but it appears to be the only practical method of combining results obtained by different methods in many different laboratories. Some authors do not specify how their published error is to be interpreted, and at best the assignment of an estimate of uncertainty to a Q value measurement involves subjective factors that vary from one individual to the next. In calculating the weighted average of several measurements, each measurement is weighted inversely as the square of the stated error. A measurement for which no error is given is necessarily omitted from the average. Range measurements have been omitted from the average if there are precise magnetic or electrostatic deflection measurements of the same reaction available. In addition, a few experimental results, designated by the superscript "c," have been omitted from the average because they appear to be statistically inconsistent with the other measurements of the same Q value. If all of the experimental measurements of a reaction energy appear to be inconsistent with each other, and there is no basis for choosing one of the measurements as most reliable, no average value has been calculated.

Inverse and direct reactions have been averaged together, and the same average value, identified by a dagger superscript, has been listed for both reactions.

In assigning an error to the weighted average, both the internal error E_{int} and the external error E_{ext} have been calculated for each reaction:

$$\frac{1}{E_{\text{int}}^2} = \sum_i^n \frac{1}{E_i^2}$$

$$E_{\text{ext}}^2 = \frac{\sum_i^n w_i (Q_i - \bar{Q})^2}{(n-1) \sum_i^n w_i}; \quad w_i = \frac{1}{E_i^2};$$

where E_i is the error of the i 'th measurement. The larger of the two errors, E_{int} or E_{ext} , is taken to be the error of the weighted average value. This method of calculating the error for the weighted average is justified only if the errors E_i are completely random. Although the E_i do contain systematic parts from the uncertainties in the fundamental constants and energy standards, the wide variety of different constants and standards used in the different measurements lends support for the above method of calculation.

The mass difference between many of the nuclides appearing in Table I can be determined in more than one way, and some care should be taken to select the reaction or set of reactions which will determine the desired mass difference with minimum uncertainty. For example, the binding energy of the last neutron in P^{32} is given as 7.94 ± 0.03 Mev by the $\text{P}^{31}(n, \gamma)\text{P}^{32}$ reaction energy: This same binding energy can be determined more accurately by adding the $\text{P}^{31}(d, p)\text{P}^{32}$ reaction energy and the binding energy of the deuteron $\text{H}^1(n, \gamma)\text{D}^2$,

$$\text{P}^{31} + \text{D}^2 = \text{P}^{32} + \text{H}^1 + 5.704 \pm 0.008 \text{ Mev}$$

$$\text{H}^1 + n = \text{D}^2 + \gamma + 2.227 \pm 0.002 \text{ Mev}$$

$$\text{P}^{31} + n = \text{P}^{32} + \gamma + 7.931 \pm 0.008 \text{ Mev}$$

with an uncertainty of only 0.008 Mev. The charts at the end of Table I provide a convenient means of finding all of the reactions or reaction cycles that can give information about a particular mass difference. On the charts a link connecting two nuclides represents a reaction listed in the table, and the mass difference between any two nuclides which are connected by a link or chain of links can be determined from the information in the table. The more accurately measured reactions, $\Delta Q \leq 20$ kev, are indicated by solid lines; dotted links indicate measurements with an uncertainty greater than 20 kev. A key in the corner of each figure identifies the type of reaction represented by different connecting links.

Nuclear reactions listed in the table are represented by links connecting target nucleus and residual nucleus. Q values with an error ≤ 20 keV are represented by solid links; dotted links are used for Q values with an error > 20 keV. The types of reactions represented by the different link configurations are indicated in the legend.

TABLE I. Nuclear reaction energies.

^a This Q value has been calculated specifically for this compilation from the experimental data. In the calculation of Q values from published threshold energies, accurate masses have been used if they are known. Mass numbers have been used if the masses are not known.

^b This Q value has been corrected for the Li⁷(p,n)Be⁷ threshold at 1.881 Mev.

^c This Q value has been omitted from the weighted average.

^d This Q value has been corrected for the F¹⁹(p, $\alpha \gamma$) resonance energy of 873.5 kev.

^e This reference contains a later correction to the value originally reported.

^f In this reference the quoted error for the Q value has been changed.

[†] This average value was calculated by including the measured Q value for the inverse reaction.

* This Q value has been calculated specifically for this compilation from the experimental data. In the calculation of Q values from published threshold energies, accurate masses have been used if they are known. Mass numbers have been used if the masses are not known.

^b This Q value has been corrected for the $\text{Li}^7(\text{p}, \text{n})\text{Be}^7$ threshold at 1.881 Mev.

^c This Q value has been omitted from the weighted average.

^d This Q value has been corrected for the $\text{P}^{31}(\text{p}, \alpha\gamma)$ resonance energy of 873.5 kev.

* This reference contains a later correction to the value originally reported.

** In this reference the quoted error for the Q value has been changed.

† This average value was calculated by including the measured Q value for the inverse reaction.

Note added in proof.—On page 408, the third line of the table should read

$\text{D}^2(\text{n}, \gamma)\text{T}^3$	6.251 ± 0.008 Mev	pr spec	absolute	Ki 50b
--	-----------------------	---------	----------	--------

Note added in proof.—On page 431 of Table I add

$\text{Rb}^{87}(\text{d}, \text{p})\text{Rb}^{88}$	-3.75 ± 0.20 Mev	scint spec		Wa ⁵⁴
--	----------------------	------------	--	------------------

List of Abbreviations Used for Experimental Methods
