Local Robust Performance Analysis for Nonlinear Dynamical Systems

Ufuk Topcu and Andrew Packard

Abstract—We propose a computational method for local robust performance analysis of nonlinear systems with polynomial dynamics. Specifically, we characterize upper bounds for local $\mathcal{L}_2 \rightarrow \mathcal{L}_2$ input-output gains using polynomial Lyapunov/storage functions satisfying certain dissipation inequalities and compute safe approximations for these upper bounds via sum-of-squares programming problems. We consider both bounded parametric uncertainties and bounded uncertainties due to unmodeled dynamics.

I. INTRODUCTION

We consider the problem of quantifying robust performance properties of uncertain nonlinear dynamical systems with polynomial vector fields around asymptotically stable equilibrium points. The amount of amplification of bounded $\mathcal{L}_2$ input norms at the output channels is used as a measure of performance. Two types of uncertainties are considered: (1) bounded uncertainties due to unmodeled dynamics and (2) bounded parametric uncertainties. Following [1], [2], [3], we characterize upper bounds on local input-output gains due to bounded $\mathcal{L}_2$ disturbances by Lyapunov/storage functions which satisfy certain “local” dissipation inequalities [4]. Similar problems were studied in [1], [2], [5], [6], [7] mainly for systems with no uncertainty. Input-output properties of uncertain nonlinear systems were examined in [8] (for discrete time nonlinear systems with a finite-time horizon performance metric) and [9] (input-output gains for sufficiently small input signals).

In this paper, we use polynomial Lyapunov/storage function candidates, simple generalizations of the S-procedure [10], and sum-of-squares (SOS) relaxations for polynomial nonnegativity [11] and compute upper bounds on the input-output gains via (bilinear) SOS programming problems. Uncertainties due to unmodeled dynamics are accounted for in the setting [12] shown in Figure 1 where M models the nominal part and Φ is an unknown operator satisfying certain relations between the input z and the output w_2 . The objective is to compute upper bounds on the $\mathcal{L}_2$ norm of the exogenous output e in terms of the $\mathcal{L}_2$ norm of the exogenous input w_1 . The approach is composed of two steps: first bound the $\mathcal{L}_2$ norm of the internal input w_2 to M in terms of the $\mathcal{L}_2$ norm of w_1 and then perform an input-output gain analysis for M from the inputs (w_1, w_2) to the output e .

The approach for the bounded parametric uncertainties is similar to that developed in [13], [14] in the context of

Fig. 1. Input-output system with the feedback interconnection of Φ and M .

robust region-of-attraction analysis. Namely, a parameter-independent Lyapunov/storage function is used to characterize input-output properties of uncertain systems over the entire set of admissible values of uncertain parameters. The input-output relations characterized by a single parameter-independent certificate may be more conservative compared to those by parameter-dependent certificates. This potential conservatism is simply reduced by partitioning the set of uncertain parameters into subregions and computing parameter-independent certificates for each subregion. The partition of the uncertainty set can be refined following ideas parallel to branch-and-bound algorithm [15] to further reduce the conservatism. Although it is simplistic (compared to techniques based on parameter-dependent Lyapunov functions), this approach offers certain computational advantages as discussed in [14] for robust region-of-attraction analysis. In fact, in robustness analysis involving time-invariant unknown parameters, it is common, [16], [17], to combine easily-computable sufficient conditions with branch-and-bound strategies, often yielding improved analysis results.

The rest of the paper is organized as follows: A characterization of upper bounds for $\mathcal{L}_2 \rightarrow \mathcal{L}_2$ input-output gains by Lyapunov/storage functions is discussed in section II. Section III is devoted to the development of the results for the case with unmodeled dynamics and this is followed by the method to account for parametric uncertainties in section IV. Implementation details are given in section V. Demonstration of the methodology with examples in section VI precedes the concluding remarks.

Notation: For $\xi \in \mathcal{R}^n$, $\xi \succeq 0$ means that $\xi_k \geq 0$ for $k = 1, \dots, n$. For $Q = Q^T \in \mathcal{R}^{n \times n}$, $Q \succeq 0$ ($Q \succ 0$) means that $\xi^T Q \xi \geq 0$ (> 0) for all $\xi \in \mathcal{R}^n$. $\mathbb{R}[\xi]$ represents the set of polynomials in ξ with real coefficients. The subset $\Sigma[\xi] := \{\pi = \pi_1^2 + \pi_2^2 + \dots + \pi_M^2 : \pi_1, \dots, \pi_M \in \mathbb{R}[\xi]\}$ of $\mathbb{R}[\xi]$ is the set of SOS polynomials. For $\pi \in \mathbb{R}[\xi]$, $\partial(\pi)$ denotes the degree of π . For $\eta > 0$ and a function $g : \mathcal{R}^n \rightarrow \mathcal{R}$, define the η -sublevel set $\Omega_{g,\eta}$ of g as

$$\Omega_{g,\eta} := \{x \in \mathcal{R}^n : g(x) \leq \eta\}.$$

U. Topcu is with Control and Dynamical Systems at California Institute of Technology, Pasadena, CA, 91125 (utopcu@cds.caltech.edu) and A. Packard is with the Department of Mechanical Engineering, The University of California, Berkeley, CA, 94720-1740, USA (pack@jagger.me.berkeley.edu).

In several places, a relationship between an algebraic condition on some real variables and state properties of a dynamical system is claimed, and same symbol for a particular real variable in the algebraic statement as well as the state of the dynamical system is used. This could be a source of confusion, so care on the reader's part is required. $\triangleleft$

II. UPPER BOUNDS ON THE $\mathcal{L}_2 \rightarrow \mathcal{L}_2$ INPUT-OUTPUT GAIN

Consider the dynamical system governed by

$$\begin{aligned}\dot{x}(t) &= f(x(t), w(t)) \\ z(t) &= h(x(t)),\end{aligned}\quad (1)$$

where $x(t) \in \mathcal{R}^n$, $w(t) \in \mathcal{R}^{n_w}$, and f is a n -vector with elements in $\mathbb{R}[(x, w)]$ such that $f(0, 0) = 0$ and h is an n_z -vector with elements in $\mathbb{R}[x]$ such that $h(0) = 0$. Let $\phi(t; x_0, w)$ denote the solution to (1) at time t with the initial condition $x(0) = x_0$ driven by the input/disturbance w . For a piecewise continuous map $u : [0, \infty) \rightarrow \mathcal{R}^m$, define the (truncated) $\mathcal{L}_2$ norm as

$$\|u\|_{2,T} := \sqrt{\int_0^T u(t)^T u(t) dt}.$$

For notational simplicity, denote $\|u\|_{2,\infty}$ by $\|u\|_2$.

A. Upper bounds on local $\mathcal{L}_2 \rightarrow \mathcal{L}_2$ gain

Lemma II.1. [2] *If there exist a real scalar $\gamma > 0$ and a continuously differentiable function V such that, for $R > 0$, Ω_{V,R^2} is bounded,*

$$\begin{aligned}V(0) = 0 \text{ and } V(x) > 0 \quad &\text{for all nonzero } x \in \mathcal{R}^n, \\ \nabla V f(x, w) \leq w^T w - \gamma^{-2} z^T z \quad &\forall x \in \Omega_{V,R^2} \text{ and } \forall w \in \mathcal{R}^{n_w},\end{aligned}\quad (2)$$

then it holds that for the system in (1) and for all $T \geq 0$

$$\|w\|_{2,T} \leq R \text{ and } x(0) = 0 \Rightarrow \|z\|_{2,T} \leq \gamma \|w\|_{2,T}.\quad (4)$$

$\triangleleft$

In other words, γ is a *local* upper bound for the input-output gain for the system in (1). We call γ to be a local upper bound because the upper bound on the norm of the output z is only supposed to hold whenever the norm of the input is bounded by R . This is unlike the input-output gains for linear systems which hold for all values of input norms.

Let $\gamma > 0$ be fixed and $\mathcal{V}$ be the space of continuously differentiable functions. Define $R_{\mathcal{L}_2, \text{opt}}(\mathcal{V}, \gamma)$ be the maximum value of R such that the conditions in Lemma II.1 hold for some $V \in \mathcal{V}$. Let $\mathcal{V}_{\text{poly}}$ be a subset of $\mathcal{V}$ that is composed of all polynomials in x of some fixed finite degree (omitted in notation). By restricting the search for V satisfying the conditions in Lemma II.1 to $\mathcal{V}_{\text{poly}}$, utilizing a generalization of the S-procedure (see Lemma VIII.1 in the Appendix) to obtain sufficient conditions for the set containment constraints in Lemma II.1 and SOS relaxations for polynomial nonnegativity, the following proposition provides an upper bound on $R_{\mathcal{L}_2, \text{opt}}(\mathcal{V}, \gamma)$.

Proposition II.1. *For given $\gamma > 0$ and positive definite polynomial l , let $R_{\mathcal{L}_2}$ be defined through*

$$R_{\mathcal{L}_2}^2(\mathcal{V}_{\text{poly}}, \mathcal{S}, \gamma, l) := \max_{V \in \mathcal{V}_{\text{poly}}, R \geq 0, s \in \mathcal{S}} R^2 \quad \text{s. t.} \quad (5)$$

$$V(0) = 0, \quad s \in \Sigma[(x, w)], \quad (6)$$

$$V - l \in \Sigma[x], \quad (7)$$

$$-[(R^2 - V)s + \nabla V f - w^T w + \gamma^{-2} z^T z] \in \Sigma[(x, w)],$$

where $\mathcal{V}_{\text{poly}} \subseteq \mathcal{V}$ is as defined above and $\mathcal{S}$ is a prescribed finite-dimensional subset of $\mathbb{R}[(x, w)]$. Then, $R_{\mathcal{L}_2}(\mathcal{V}_{\text{poly}}, \mathcal{S}, \gamma, l) \leq R_{\mathcal{L}_2, \text{opt}}(\mathcal{V}, \gamma)$. $\triangleleft$

Note that $R_{\mathcal{L}_2, \text{opt}}$ depends on γ and $\mathcal{V}$ and $R_{\mathcal{L}_2}$ depends on $\mathcal{V}_{\text{poly}}$, $\mathcal{S}$, ϵ , l , and γ . Hereafter, this dependence will not be notated explicitly unless it causes confusion.

The optimization problem in Proposition II.1 can be cast in a bilinear SDP (i.e., nonconvex in general). Bilinear SDPs are known to be harder than linear ones [18]. Consequently, the state-of-the-art of the solvers for bilinear SDPs is far behind that for the linear ones and methods for bilinear SDPs are generally based on heuristics such as coordinate-wise affine search or specialized solvers e.g. PENBMI[19]. Although these techniques are local search schemes and convergence to a global optimum is not guaranteed, coupled with efficient initializations, they have been effectively used for several system analysis questions [20], [21]. For the examples in this paper, we use a coordinatewise affine search scheme as detailed in section V.

For given $\gamma > 0$, the optimization problem in Proposition II.1 maximizes R (that can be verified through the families of admissible Lyapunov function candidates (V) and S-procedure multipliers (s)) such that $\|z\|_2 \leq \gamma \|w\|_2$ whenever $\|w\|_2 \leq R$. One can also choose to minimize γ for a given value of R and this can be formulated as an optimization problem similar to that in Proposition II.1 with minor changes.

III. ROBUST PERFORMANCE IN THE PRESENCE OF UNMODELED DYNAMICS

Consider the input-output system in Figure 1. Let

$$\begin{aligned}\dot{x}(t) &= f(x(t), w_1(t), w_2(t)) \\ z(t) &= h_1(x(t)) \\ e(t) &= h_2(x(t))\end{aligned}\quad (14)$$

be a realization of M , where $w_1(t) \in \mathcal{R}^{n_{w_1}}$, $w_2(t) \in \mathcal{R}^{n_{w_2}}$, f is an n -vector of polynomials in $\mathbb{R}[(x, w_1, w_2)]$ with $f(0, 0, 0) = 0$, h_1 and h_2 are n_z and n_e dimensional vectors with entries in $\mathbb{R}[x]$ satisfying $h_1(0) = 0$ and $h_2(0) = 0$. Furthermore, assume that Φ is causal and, starting from rest, satisfies

$$\|\Phi(z)\|_{2,T} = \|w_2\|_{2,T} \leq \|z\|_{2,T} \quad (15)$$

for all $T \geq 0$. Lemma III.1 provides a bound on $\|w_2\|_{2,T}$ in terms of $\|w_1\|_{2,T}$ for $T \geq 0$. In the following proposition, this result will be used to establish a local upper bound on the norm of the exogenous output e in terms of the norm of the exogenous input w_1 .

$$R_1^2 := \max_{V \in \mathcal{V}_{poly}, R \geq 0, s \in \mathcal{S}} R^2 \quad \text{subject to} \quad (8)$$

$$V(0) = 0, \quad s \in \Sigma[(x, w_1, w_2)], \quad V - l \in \Sigma[x], \quad (9)$$

$$- [(R^2 - V)s + \nabla V f(x, w_1, w_2) - (\beta^2 w_1^T w_1 + w_2^T w_2) + \alpha^{-2} z^T z] \in \Sigma[(x, w_1, w_2)], \quad (10)$$

$$\gamma_1 := \min_{Q \in \mathcal{V}_{poly}, \gamma > 0, s \in \mathcal{S}} \gamma \quad \text{subject to} \quad (11)$$

$$Q(0) = 0, \quad s \in \Sigma[(x, w_1, w_2)], \quad Q - l \in \Sigma[x], \quad (12)$$

$$- \left[\left(\frac{R_1^2}{1-\alpha^2} - Q \right) s + \nabla Q f(x, w_1, w_2) - (\beta^2 w_1^T w_1 + w_2^T w_2) + \gamma^{-2} e^T e \right] \in \Sigma[(x, w_1, w_2)]. \quad (13)$$

Lemma III.1. For $R > 0$, $0 < \alpha < 1$ and $\beta > 0$, if there exists a continuously differentiable, positive definite function V such that $V(0) = 0$, Ω_{V,R^2} is bounded, and

$$\nabla V f(x, w_1, w_2) \leq \beta^2 w_1^T w_1 + w_2^T w_2 - \frac{1}{\alpha^2} z^T z$$

for all $x \in \Omega_{V,R^2}$, $w_1 \in \mathcal{R}^{n_{w_1}}$, and $w_2 \in \mathcal{R}^{n_{w_2}}$, then for Φ starting from rest and for all $T \geq 0$

$$x(0) = 0 \text{ and } \|w_1\|_{2,T} \leq \frac{R}{\beta} \Rightarrow \|w_2\|_{2,T} \leq \frac{\alpha R}{\sqrt{1-\alpha^2}}.$$

◁

Proof: While solutions to (14) exist, for $T \geq 0$

$$\begin{aligned} \beta^2 \|w_1\|_{2,T}^2 + \|w_2\|_{2,T}^2 - \frac{1}{\alpha^2} \|z\|_{2,T}^2 \\ \leq \beta^2 \|w_1\|_{2,T}^2 - \frac{1-\alpha^2}{\alpha^2} \|z\|_{2,T}^2 \leq \beta^2 \|w_1\|_{2,T}^2. \end{aligned} \quad (16)$$

Since Ω_{V,R^2} is bounded, as long as

$$\|w_1\|_{2,T} \leq \frac{\sqrt{R^2 - V(x(0))}}{\beta}$$

solutions to (14) exist for all $T \geq 0$ and satisfy

$$\|w_2\|_{2,T}^2 \leq \|z\|_{2,T}^2 \leq \frac{\alpha^2 \beta^2}{1-\alpha^2} \|w_1\|_{2,T}^2 + \frac{\alpha^2}{1-\alpha^2} V(x(0)).$$

In particular, for $x(0) = 0$, $V(x(0)) = 0$ and $\|w_2\|_{w,T} \leq \frac{\alpha R}{\sqrt{1-\alpha^2}}$. ◻

Proposition III.1. In addition to the conditions in Lemma III.1, if there exists a continuously differentiable, positive definite function Q such that $Q(0) = 0$ and

$$\nabla Q f(x, w_1, w_2) \leq \beta^2 w_1^T w_1 + w_2^T w_2 - \frac{1}{\gamma^2} e^T e$$

for all $x \in \Omega_{Q,R^2/(1-\alpha^2)}$, $w_1 \in \mathcal{R}^{n_{w_1}}$, $w_2 \in \mathcal{R}^{n_{w_2}}$, then for Φ starting from rest and for all $T \geq 0$

$$\|w_1\|_{2,T} \leq \frac{R}{\beta} \text{ and } x(0) = 0 \Rightarrow \|e\|_{2,T} \leq \gamma R / \sqrt{1-\alpha^2}.$$

◁

Proof: By Lemma III.1,

$$\|w_1\|_{2,T} \leq R/\beta \Rightarrow \beta^2 \|w_1\|_{2,T}^2 + \|w_2\|_{2,T}^2 \leq \frac{R^2}{1-\alpha^2}.$$

Consequently, the result follows from Lemma II.1. ◻

Lemma III.1 and Proposition III.1 can be used to construct relations between $\|w_1\|_{2,T}$ and $\|e\|_{2,T}$. Similar to Proposition II.1, one can obtain sufficient conditions for those in Lemma III.1 and Proposition III.1 using Lemma VIII.1 and SOS relaxations for polynomial nonnegativity. For given $\beta > 0$, $\alpha > 0$, and $l(x) = \epsilon x^T x$ (with $\epsilon > 0$ fixed), solve the problems in (8)-(10) and (11)-(13). Then, for Φ starting from rest and for all $T \geq 0$

$$x(0) = 0 \text{ and } \|w_1\|_{2,T} \leq \frac{R_1}{\beta} \Rightarrow \|e\|_{2,T} \leq \frac{\gamma R_1}{\sqrt{1-\alpha^2}}.$$

When Φ is unknown but a global gain relation between its inputs and outputs is known, then the results of this section provide a framework for robust performance analysis for the feedback interconnection between M and Φ . On the other hand, even when the operator Φ is known, the procedure outlined in this section can be used as a framework for compositional performance analysis. Note that conditions in Lemma III.1 and Proposition III.1 do not involve the states of (the realization of) Φ . When Φ has the state space realization $\dot{x}_2(t) = f_2(x_2(t), z(t))$, then the gain relation $\|\Phi(z)\|_{2,T} \leq \|z\|_{2,T}$ can be established by determining a positive definite, continuously differentiable function V_2 satisfying

$$\nabla V_2 f_2(x_2, z) \leq z^T z - w_2^T w_2 \quad \forall x_2 \in \mathcal{R}^{n_2}, \quad \forall z \in \mathcal{R}^{n_z}$$

which does not depend on the states x_1 of M . Consequently, Lemma III.1 and Proposition III.1 enable performance analysis for the feedback interconnection between M and Φ based on the input-output properties of individual blocks. Of course, this analysis may be conservative. Nevertheless, compositional analysis may be a fruitful direction which extends the applicability of SOS programming based non-linear analysis tools for reasonably larger dimensional systems whenever it is possible to establish an interconnection structure as in Figure 1. Furthermore, it may be possible to refine the input-output relations between w_1 and e by using transformations at the interconnections similar to the D scales in linear robustness analysis [12].

IV. ROBUST PERFORMANCE ANALYSIS IN THE PRESENCE OF PARAMETRIC UNCERTAINTIES

We now generalize the development in section II to the case where the vector field contains unknown but fixed and bounded parameters. Following the methodology proposed in [14] in the context of robust stability analysis, we first restrict our attention to

$$\begin{aligned}\dot{x}(t) &= f(x, w, \delta) \\ &:= f_0(x(t), w(t)) + \sum_{i=1}^m \delta_i f_i(x(t), w(t)) \quad (17) \\ z(t) &= h(x(t)),\end{aligned}$$

where $f_0, f_1, \dots, f_m$ are n -vectors with elements in $\mathbb{R}[(x, w)]$ such that $f_0(0, 0, \delta) = f_1(0, 0, \delta) = \dots = f_m(0, 0, \delta) = 0$, for all $\delta \in \Delta \subset \mathcal{R}^m$, and Δ is a known bounded polytope. Let $\phi(t; x_0, w, \delta)$ denote the solution of (17) for δ at time t with the initial condition $x(0) = x_0$ driven by the input/disturbance w and $\mathcal{E}_\Delta$ denote the set of vertices of Δ .

Proposition IV.1. *If there exist a real scalar $\gamma > 0$ and a continuously differentiable function V such that $V(0) = 0$, $V(x) > 0$ for all nonzero $x \in \mathcal{R}^n$, Ω_{V, R^2} is bounded, and*

$$\nabla V f(x, w, \delta) \leq w^T w - \gamma^{-2} z^T z \quad (18)$$

for all $x \in \Omega_{V, R^2}$, $w \in \mathcal{R}^{n_w}$, and $\delta \in \mathcal{E}_\Delta$, then the system in (17) with $x(0) = 0$ satisfies $\|z\|_2 \leq \gamma \|w\|_2$ whenever $\|w\|_2 \leq R$ and $\delta \in \Delta$. $\triangleleft$

Proof: Since the vector field is affine in δ and Δ is a bounded polytope, it follows that, for $\delta \in \Delta$, $\nabla V f(x, w, \delta) \leq w^T w$ for all $x \in \Omega_{V, R^2}$, $w \in \mathcal{R}^{n_w}$. By Lemma II.1, for each $\delta \in \Delta$, $\|z\|_2 = \|h(\phi(\cdot; 0, w, \delta))\|_2 \leq \gamma \|w\|_2$ whenever $\|w\|_2 \leq R$. $\square$

Note that restricting the attention to affine uncertainty δ dependence and polytopic Δ , Proposition IV.1 enables to compute upper bounds on $\mathcal{L}_2 \rightarrow \mathcal{L}_2$ gain for the system in (17) by imposing the conditions in (18) at finitely many $\delta \in \mathcal{E}_\Delta$ instead of at infinitely many $\delta \in \Delta$. Furthermore, sufficient conditions for those in Proposition IV.1 can be obtained using Lemma VIII.1 and SOS relaxations.

The approach proposed here is restrictive: (1) only affine dependence on δ and polytopic Δ are allowed (2) SOS relaxations for the conditions in Proposition IV.1 may include a large number of SDP constraints (3) single (δ -independent) Lyapunov/storage function is to certify properties for an entire family of systems. These limitations can be partially alleviated using techniques proposed in [14] in the context of robust region-of-attraction analysis. For example, polynomial dependence on δ in the vector field and the output map can be handled by covering the graph of non-affine functions δ (in the conditions in Proposition IV.1) by bounded polytopes. Furthermore, the fact that constraints in the SOS relaxations for the conditions in IV.1 are only coupled through the Lyapunov/storage functions (which include relatively small portion of all decision variables in associated SDPs) can be exploited through a suboptimal two-step procedure: pick a point in Δ , compute a Lyapunov/storage function for the system corresponding to that point, and then in the

second step determine an input-output relation certified by the Lyapunov/storage function determined (fixed) in the first step which holds for the entire family of admissible systems. This procedure effectively decouples the large number of constraints in the second step enabling use of trivial parallelization. Finally, conservatism (due to using a single parameter-independent Lyapunov function and due to the suboptimal two-step procedure) can be reduced by an informal branch-and-bound type refinement procedure where Δ is partitioned into smaller subregions and a different Lyapunov/storage function is computed for each subregion. See [14] which develops a similar methodology in the context of robust region-of-attraction analysis.

V. IMPLEMENTATION ISSUES

The SOS relaxations in (5)-(7) lead to bilinear SDPs due to the multiplication between the decision variables in V and the multipliers. Therefore, solution techniques for these problems are usually limited to local search schemes such as PENBMI [19] or coordinate-wise affine search based on the observation that, for given V and R , constraints in these problems are affine in the decision variables in the multipliers. For example, one can obtain a suboptimal solution for the problem in (5)-(7) by alternatingly solving the following two problems until a maximum number of iterations is reached or the increase in the value of certified R becomes smaller than a pre-specified tolerance. For given V

$$\max_{R>0, s \in S} R^2 \text{ subject to } s \in \Sigma[(x, w)] \text{ and (7),} \quad (19)$$

which can be solved using an off-the-shelf affine SDP solver through a line search on R , and for given (feasible) multiplier s

$$\max_{R>0, V \in \mathcal{V}_{poly}} R^2 \text{ subject to } V-l \in \Sigma[x], V(0) = 0, \text{ and (7).} \quad (20)$$

Furthermore, by a change of variables, it is possible to iterate without a line search in the first step. Indeed, for $\beta > 0$, if the problem in (5)-(7) has the solution R_l^2, V_l and s_l , then

$$\begin{aligned}\frac{1}{R_l^2} &= \min_{K \in \mathcal{V}_{poly}, 1/R^2 > 0, \tilde{s} \in S} \frac{1}{R^2} \text{ subject to} \\ \tilde{s} &\in \Sigma[(x, w)], K \in \mathbb{R}[x], K - l_1/R^2 \in \Sigma[x], \\ &- [(1-K)\tilde{s} + \nabla K f - \frac{1}{R^2}(w^T w - \gamma^{-2} z^T z)] \\ &\in \Sigma[(x, w)].\end{aligned} \quad (21)$$

Note that for given K constraints in (21) are affine in $1/R^2$ and $\tilde{s}$. In fact, optimal values of $\tilde{s}$ and K are $\tilde{s} = R_l^2 s_l$, and $K = V_l/R_l^2$.

VI. EXAMPLES

Consider the controlled short period aircraft dynamics in Figure 2 where $x_p := [x_1 \ x_2 \ x_3]^T$, x_1 , x_2 , and x_3 denote the pitch rate, the angle of attack, and the pitch angle,

Fig. 2. Controlled short period aircraft dynamics with unmodeled dynamics.

respectively, and

$$\dot{x}_p = \begin{bmatrix} c(x_p) \\ q(x_p) \\ x_1 \end{bmatrix} + \begin{bmatrix} \ell_b^T x_p + b_1 \\ b_2 \\ 0 \end{bmatrix} u, \quad (22)$$

where, c and q are cubic and quadratic polynomials, respectively, $\ell_b \in \mathcal{R}^3$, b_1 and b_2 are real scalars (see [22] for the values of the missing parameters). The plant output is $[x_1 \ x_3]^T$. The input u to the plant is

$$u = 1.25v + w_1 + w_2$$

where v , the elevator deflection, is the controller output determined by

$$\begin{aligned} \dot{x}_4 &= -0.864y_1 - 0.321y_2 \\ v &= 2x_4, \end{aligned}$$

where x_4 is the controller state. Assume that $\Phi : \mathcal{R} \rightarrow \mathcal{R}$ satisfies, starting from rest,

$$\|\Phi(z)\|_{2,T} = \|w_2\|_{2,T} \leq \|z\|_{2,T}$$

for all $T \geq 0$. We performed the following analysis:

- (i) For several values of $\alpha \in [0.55, 0.9]$, solve the problems in (8)-(10) and (11)-(13).
- (ii) Apply linearized robust performance analysis for the feedback interconnection [23] and fit a first order stable minimum phase transfer function, say $H(s)$, to the optimal D-scales. For several values of $\alpha \in [0.55, 0.9]$, solve the problems in (8)-(10) and (11)-(13) for the system HMH^{-1} with a minimal realization for H .
- (iii) Solve the problem in Proposition II.1 for the system with no uncertainty for several values of γ .

Figure 3 shows the $\mathcal{L}_2$ norms of the exogenous outputs e versus the $\mathcal{L}_2$ norms of the exogenous inputs w_1 in each of these cases: (i) with marker “+”, (ii) with marker “•”, and (iii) with marker “×”.

Figure 3 illustrates the trade off between the robustness and performance: As α gets larger, the gap between the nominal performance level and the “robust” performance level increases deduced from the divergence between the curve with “+” and other two curves.

VII. CONCLUSION

We proposed a computational method for local robust performance analysis of nonlinear systems with polynomial dynamics. Specifically, we characterized upper bounds for local $\mathcal{L}_2 \rightarrow \mathcal{L}_2$ input-output gains using polynomial Lyapunov/storage functions satisfying certain dissipation

inequalities and computed safe approximations for these upper bounds via sum-of-squares programming problems. We considered both bounded parametric uncertainties and bounded uncertainties due to unmodeled dynamics.

VIII. APPENDIX

The following lemma is a simple generalization of the S-procedure [10] and is used to obtain sufficient conditions for certain set containment constraints throughout the paper.

Lemma VIII.1. For $g_0, g_1, \dots, g_m \in \mathbb{R}[x]$, if there exist $s_1, \dots, s_m \in \Sigma[x]$ such that

$$g_0 - \sum_{i=1}^m s_i g_i \in \Sigma[x],$$

then

$$\begin{aligned} \{x \in \mathcal{R}^n : g_1(x), \dots, g_m(x) \geq 0\} \\ \subseteq \{x \in \mathcal{R}^n : g_0(x) \geq 0\}. \end{aligned}$$
