15 **Abstract**

16 Type IV secretion systems (T4SSs) are large macromolecular machines that translocate
17 protein and DNA and are involved in the pathogenesis of multiple human diseases. Here,
18 using electron cryotomography (ECT), we report the *in situ* structure of the Dot/Icm type
19 IVB secretion system (T4BSS) utilized by the human pathogen *Legionella pneumophila*.
20 This is the first structure of a type IVB secretion system, and also the first structure of
21 any T4SS *in situ*. While the Dot/Icm system shares almost no sequence homology with
22 type IVA secretion systems (T4ASSs), its overall structure shows remarkable similarities
23 to two previously imaged T4ASSs, suggesting shared aspects of mechanism. However,
24 compared to one of these, the negative-stain reconstruction of the purified T4ASS from
25 the R388 plasmid, it is approximately twice as long and wide and exhibits several
26 additional large densities, reflecting type-specific elaborations and potentially better
27 structural preservation *in situ*.

28 **Introduction**

29 Type IV secretion systems (T4SSs) are found ubiquitously in Gram-negative and Gram-
30 positive bacteria as well as in some archaea (Wallden et al, 2010). They exchange genetic
31 material within and across kingdoms and translocate virulence factors into host cells
32 (Chandran Darbari & Waksman, 2015). T4SSs have been classified into two major
33 groups, type IVA and type IVB (Chandran Darbari & Waksman, 2015; Sexton & Vogel,
34 2002). Representative examples of T4ASSs include many conjugative plasmids such as
35 F, RP4, R388, and pKM101 and the VirB T4SS (VirB1-11 and VirD4) of the plant
36 pathogen *Agrobacterium tumefaciens* (Chandran Darbari & Waksman, 2015; Christie et
37 al, 2005). The VirB system is one of the best characterized T4ASSs and consists of a lytic
38 transglycosylase (VirB1), pilins (VirB2 and VirB5), inner membrane proteins (VirB3,
39 VirB6, VirB8), ATPases (VirB4, VirB11 and VirD4) and three factors (VirB7, VirB9,
40 VirB10) that span the inner and outer membrane (Chandran Darbari & Waksman, 2015).

41

42 Based on major differences in composition and sequence, a subset of T4SSs were
43 designated as T4BSSs (Sexton & Vogel, 2002). T4BSSs include the IncI conjugative
44 plasmids R64 and ColIb-P9 and the Dot/Icm (defective in organelle
45 trafficking/intracellular multiplication) system of the pathogens *Legionella pneumophila*,
46 *Coxiella burnetii*, and *Rickettsiella grylli* (Chandran Darbari & Waksman, 2015; Christie
47 et al, 2005; Segal et al, 2005). In the case of *L. pneumophila*, the Dot/Icm system
48 translocates more than 300 effector proteins into host cells (Isaac & Isberg, 2014),
49 thereby allowing the pathogen to survive and replicate within phagocytic host cells (Segal
50 et al, 1998; Vogel et al, 1998). The Dot/Icm T4BSS is more complex than most T4ASSs

51 as it has ~27 components versus 12. The only clear sequence homology between T4A
52 and T4B components is the C-terminus of DotG, which matches part of VirB10 (Nagai &
53 Kubori, 2011). The Dot ATPases (DotB, DotL, DotO) are also of the same general
54 classes of proteins as the *A. tumefaciens* ATPases (VirB11, VirD4, VirB4). Based on
55 relationships between ATPases, T4SSs have recently been reclassified into eight classes,
56 with the IncI class being one of the most distinct (Guglielmini et al, 2014). How similar
57 the structures and functions of different T4SSs are remains unclear.

58

59 Great efforts have been invested into structurally characterizing different T4ASSs using
60 an impressive array of biochemistry, crystallography and EM (Chandran Darbari &
61 Waksman, 2015; Chandran et al, 2009; Fronzes et al, 2009; Low et al, 2014; Pena et al,
62 2012; Rivera-Calzada et al, 2013). The most notable achievements include a crystal
63 structure of parts of VirB7, VirB9, and VirB10 from pKM101 (3JQO) (Chandran et al,
64 2009), two cryo-EM structures of the same complex (Fronzes et al, 2009), and a negative
65 stained EM reconstruction of the recombinantly purified VirB₃₋₁₀ complex of the related
66 R388 plasmid (Low et al, 2014). The features of the VirB₃₋₁₀ reconstruction were
67 described as consisting of a periplasmic complex (cap, outer-layer, inner-layer), linked by
68 a relatively thin stalk to an inner membrane complex (upper tier, middle tier, and a lower
69 tier), with the latter forming two barrel-shaped densities that correspond to the VirB4
70 ATPase extending into the cytoplasm. However, to date no structure has been reported
71 for any T4SS *in situ* or any of the T4BSSs. Considering their distinct genetic organization
72 and composition, whether and how the T4A and T4B types are structurally related
73 remains unclear.

74

75 **Results and discussion**

76 To generate the first three-dimensional structure of a T4BSS, here we used ECT to
77 visualize *L. pneumophila* Dot/Icm machines directly in intact, frozen-hydrated bacteria
78 cells. In our tomograms, we observed multiple dense, cone-shaped particles in the
79 periplasm primarily near the cell poles (Figure 1a,b; Supplementary Movie 1). These
80 structures exhibited the characteristic shape of a “Wi-Fi” symbol comprising two distinct
81 curved layers, the larger just below the outer membrane and the smaller in the middle of
82 the periplasm (Figure 1c). We also observed top views of these particles, which appeared
83 to have two concentric rings (Figure 1d). Similar rings were observed by EM imaging of
84 portions of the Dot/Icm complex (Kubori et al, 2014). No “Wi-Fi” particles were
85 observed in a *L. pneumophila* strain lacking the *dot/icm* genes (Figure 1E, Supplementary
86 Figure 1).

87

88 To further investigate the molecular architecture of these complexes, we generated a
89 subtomogram average using ~400 particles. In the initial average, substructures were
90 resolved within the curved layers but details were lacking near the inner membrane
91 (Supplementary Figure 2A-D). Given the previous observation of flexibility within the
92 VirB₃₋₁₀ complex (Low et al, 2014), we used masks to align components near the outer
93 membrane separately from the components near the inner membrane (Supplementary
94 Figure 2 A-D). A composite average was then constructed by juxtaposing the well-
95 aligned regions of the outer and inner membrane averages and applying symmetry. In the
96 final composite average, many distinct densities were resolved including a hat, alpha, and

97 beta densities near the outer membrane; a stem, stalk, and gamma densities in the
98 periplasmic region; and weaker densities, which we call "wings", extending from the
99 inner membrane into the periplasm (Figure 1F, 1G). Although of lower resolution,
100 multiple vertical rod-like densities also appeared below the inner membrane in the
101 cytoplasm. We estimate the local resolution of our composite model to be 2.5-4.5 nm
102 (Supplementary Figure 3A), likely limited by inherent flexibility of the complex, as the
103 resolution within the curves layers was the highest and the rods the lowest.

104

105 To confirm the "Wi-Fi" particles were the Dot/Icm system, we imaged a strain expressing
106 DotC, DotD, DotF, DotG, and DotH (previously defined as the "core complex"(Vincent
107 et al, 2006)) in an otherwise *dot/icm* null mutant strain (Figure 1H). Western blot analysis
108 showed all five proteins were expressed at similar levels to those in the wild-type strain
109 (Supplementary Figure 1). The subtomogram average of this reconstituted complex
110 revealed a strong similarity to the wild-type structure as it contained the hat, beta, and
111 gamma densities and some of the stem, but there were also major densities missing
112 (Figure 1H and Supplementary Figure 3B, 3C). Since the "Wi-Fi" particles were not
113 observed in a strain lacking the *dot/icm* genes, and a portion but not all of the complex
114 reappeared upon reintroduction of the five core Dot proteins, we are confident that these
115 particles are the Dot/Icm system rather than some other membrane complex such as the
116 *L. pneumophila* T2SS or a different T4SS.

117

118 In T4ASSs, a "core complex" has been described consisting of three proteins with major
119 domains in the periplasm: the inner membrane protein VirB10, the outer membrane

120 protein VirB9, and a lipoprotein VirB7, which plays a role in the insertion of VirB9
121 (Chandran Darbari & Waksman, 2015). In the *Legionella* T4BSS, DotF and DotG are
122 inner-membrane proteins, DotH is an outer membrane, and there are two lipoproteins,
123 DotC and DotD, that function to insert DotH (Vincent et al, 2006) Markedly, and as
124 mentioned above, among these proteins there is only one domain shared between the Dot
125 and VirB systems: the C-terminus of DotG has clear sequence homology to VirB10
126 (Chandran Darbari & Waksman, 2015). Despite this paucity of homology between
127 components, the *in situ* structure of the Dot/Icm T4BSS and the negative-stain
128 reconstruction of the VirB₃₋₁₀ T4ASS complex clearly share key features. First, the size
129 and shape of the hat density in the Dot/Icm apparatus matches the VirB10 density from
130 the crystal structure 3JQO, which contains parts of VirB7, VirB9, and VirB10 (Figure
131 2A-C, Supplementary Movie 2). This makes sense because the domain of VirB10 present
132 in the crystal structure is the one with sequence homology to DotG (Supplementary
133 Figure 4B). Thus it is not surprising that there would be a similar-shaped feature in the
134 equivalent location of the Dot/Icm structure (as seen in the hat). Both the Dot/Icm and
135 VirB₃₋₁₀ structures also contain flexible stalks between the outer membrane and inner
136 membrane complexes. Finally, the four rod-like densities in the Dot/Icm structure
137 correspond well in size, shape and position (with respect to both the inner membrane and
138 stalk) to the walls of the two barrels seen in the VirB₃₋₁₀ complex, leading us to conclude
139 that there are two similar barrels present in the Dot/Icm complex, even though they are
140 poorly resolved (Figure 2A, 2D, 2G-H). Thus the basic architecture of the Dot/Icm
141 system is strikingly similar to that of the VirB₃₋₁₀ complex: each contains a hat, stalk, and
142 two off-axis cytoplasmic barrels.

143

144 However, there are also major differences. First, the Dot/Icm complex is strikingly larger
145 than the VirB₃₋₁₀ complex, as it is approximately twice as wide and long (Figure 2G-H).
146 Second, there are no densities in the VirB₃₋₁₀ complex peripheral to the hat which might
147 correspond to alpha and beta. Third, it is not clear if the Dot/Icm gamma density is part of
148 what was described as the inner layer of the VirB₃₋₁₀ complex. Fourth, the Dot/Icm
149 structure has periplasmic wings instead of membrane-associated arches. While some of
150 these differences are likely due to the additional factors present in the Dot/Icm system,
151 others may reflect the loss or collapse of components in the VirB₃₋₁₀ complex upon
152 purification and drying. The arches of the VirB₃₋₁₀ complex, for instance, may correspond
153 to collapsed Dot/Icm wings, and the shorter and thinner stalk in the VirB₃₋₁₀ complex may
154 also be a result of collapse (the distance between the outer and inner membranes in our
155 cryotomograms of different species of intact bacterial cells is typically ~40 nm (Chang et
156 al, 2016; Chen et al, 2011), twice as far as in the VirB₃₋₁₀ complex structure).

157

158 Recently, two-dimensional class average images of a negatively-stained *H. pylori* T4ASS
159 comprising Cag3, CagM, CagT/VirB7, CagX/VirB9 and CagY/VirB10 were reported
160 (Figure 2E-F) (Frick-Cheng et al, 2016). While the *Helicobacter* T4ASS consists of
161 approximately the same number of components as the *Legionella* Dot/Icm T4BSS, the
162 additional factors share no homology (Frick-Cheng et al, 2016). Despite also being
163 purified, dried, and negatively-stained like the R388 plasmid VirB₃₋₁₀ complex, the
164 *Helicobacter* structure has almost exactly the same size and overall shape as the
165 periplasmic region of the *Legionella* structure, with a large bulbous structure at one end

166 and a stalk at the other (Figure 2A, 2E-F). Because the *Helicobacter* images were of a
167 purified subcomplex, it was impossible at the time to assign an orientation of the
168 structure relative to the envelope (Frick-Cheng et al, 2016). Based on the similarities to
169 our *in situ* structure, we can now predict that the concave surface faces the outer
170 membrane and the stalk points in the direction of the inner membrane.

171

172 In summary, we have revealed the first *in situ* structure of a T4SS and shown that despite
173 very little sequence homology between representative T4ASSs and T4BSSs
174 (Supplementary Figure 4A,B), their basic architectures and therefore likely secretion
175 mechanisms are remarkably similar. They are much more similar than different when
176 compared to the structure of other secretion systems. Type III secretion systems, for
177 example, consist of a series of rings in the inner membrane, periplasm and outer
178 membrane connected by a central channel that serves as the conduit for protein export
179 (Hu et al, 2015). In contrast, neither the T4ASS nor the T4BSS exhibit an obvious tube-
180 like channel along the symmetry axis through which substrates might be transported.
181 Although informative within its own right, the *in situ* Dot/Icm structure also sets the stage
182 for future work identifying each protein in the complex and elucidating how this
183 elaborate nanomachine assembles and functions.

184 **Materials and methods:**

185 *Strains, growth conditions and mutant generation*

186 All experiments mentioned here were performed using the *L. pneumophila* Lp02 strain
187 (*thyA hsdR rpsL*), which is a derivative of the clinical isolate *L. pneumophila*
188 Philadelphia-1. *L. pneumophila* strains were grown on ACES [N-(2-acetamido)-2-
189 aminoethanesulfonic acid]-buffered charcoal yeast extract agar (CYE) or in ACES-
190 buffered yeast extract broth (AYE) supplemented with ferric nitrate and cysteine
191 hydrochloride. Since Lp02 is a thymidine auxotroph, cells were always grown in the
192 presence of thymidine (100 µg/ml). JV5443 is a derivative of Lp02 lacking the *dot/icm*
193 genes (JV5319) that was transformed with plasmid pJB4027, which expresses *dotD*,
194 *dotC*, *dotH*, *dotG*, and *dotF*.

195

196 *Sample preparation for electron cryotomography*

197 *L. pneumophila* (Lp02) cells were harvested at early stationary phase (OD600 of ~3.0),
198 mixed with 10-nm colloidal gold beads (Sigma-Aldrich, St. Louis, MO) precoated with
199 BSA, and applied onto freshly glow-discharged copper R2/2 200 Quantifoil holey carbon
200 grids (Quantifoil Micro Tools GmbH, Jena, Germany). Grids were then blotted and
201 plunge-frozen in a liquid ethane/propane mixture (Chang et al, 2016) using an FEI
202 Vitrobot Mark IV (FEI Company, Hillsboro, OR) and stored in liquid nitrogen for
203 subsequent imaging.

204

205 *Electron tomography and subtomogram averaging*

206 Tilt-series were recorded of frozen *L. pneumophila* (Lp02) cells in an FEI Titan Krios
207 300 kV field emission gun transmission electron microscope (FEI Company, Hillsboro,
208 OR) equipped with a Gatan imaging filter (Gatan, Pleasanton, CA) and a K2 Summit
209 direct detector in counting mode (Gatan, Pleasanton, CA) using the UCSF Tomography
210 software (Zheng et al, 2007) and a total dose of ~ 100 e/A² per tilt-series and target
211 defocus of ~ 6 μ m underfocus. Images were aligned, CTF corrected, and reconstructed
212 using IMOD(Kremer et al, 1996). SIRT reconstructions were produced using
213 TOMO3D(Agulleiro & Fernandez, 2015) and subtomogram averaging was performed
214 using PEET (Nicastro et al, 2006). Finally, the local resolution was calculated by ResMap
215 (Kucukelbir et al, 2014). As the Dot/Icm subtomogram average exhibited at least two-
216 fold symmetry around the central mid-line in the periplasm, we applied two-fold
217 symmetry in those regions to produce the 2-D figures shown, but no symmetry was
218 applied to the cytoplasmic densities due to their poor resolution.

341 al, 2014)). **D**, Isosurface of (left) and cross-section (right) through a single particle
342 reconstruction of a purified VirB4 ATPase (EMDB accession #, EM-5505, reproduced
343 from Pena et al (Pena et al, 2012)). Because it is a hexameric barrel-shaped structure, its
344 cross section is two parallel rod-like densities similar to the cytoplasmic densities found
345 in the Dot/Icm structure *in situ* (outlined in yellow in panel A). **E**, Class average images
346 of a purified *H. pylori* T4ASS subcomplex comprising Cag3, CagM, CagT/VirB7,
347 CagX/VirB9, CagY/VirB10 in top and side views (reproduced from Frick-Cheng et al
348 (Frick-Cheng et al, 2016)). **F**, Same side view as in **E** but rotated and enlarged to the
349 same scale as the Dot/Icm structure. Outline marked in white and superimposed on
350 Dot/Icm structure in panel A. **G,H**, Schematic representations of a T4BSS (left) and a
351 T4ASS (right, adapted from Low et al (Low et al, 2014)) showing dimensions,
352 underlying structural similarities and differences. Scale bar for all panels except **E** 10 nm.
353 Scale bar for panel **E**, 25 nm.
