We investigate the way in which four-wave mixing in a waveguide is affected by chromatic dispersion. The frequency dependence of the associated phase-conjugate mirror reflectivity turns out not to be influenced by chromatic dispersion itself.

Degenerate four-wave mixing is investigated both in the stationary regime (in which dispersion has no role) and in the nonstationary regime (in which the time behavior of the phase-conjugate signal is important, as when one is studying the frequency response of a phase-conjugate mirror), without taking into account chromatic dispersion. Although this circumstance can be a priori justifiable over the short crystal samples in which four-wave mixing is usually performed, one is conversely led to think that chromatic dispersion can no longer be ignored when the process takes place in long glass fibers.

In this Letter, we study the time-dependent behavior of the phase-conjugate reflected signal by including in the equation describing its evolution the contribution that is due to chromatic dispersion, that is, a term containing $1/V = (d^2/da^2)^{-1}$, where $1/V$ is the group velocity and the group-velocity dispersion inside the medium, which generalizes the system of equations describing degenerate four-wave mixing in thin media (where one can put $1/V = 1/A = 0$) and in relatively thick media $^{4,5}$ ($1/A = 0$). The coefficients $S$ and $P$ are given by

$$S = 2\alpha w_0 (n_2/c)\beta^2 (\Phi_1^2 + \Phi_2^2)$$

and

$$P = 2\alpha w_0 (n_2/c)\Phi_1 \Phi_2,$$

where $\alpha$ is the central angular frequency, $\beta(w_0)$ is the associated propagation constant, and $\Phi_1$ and $\Phi_2$ are slowly varying amplitudes.

Let us write the analytic signals of the electric fields associated with the incident and reflected waves in the form (see Fig. 1)

$$E_i(x, y) = E(x, y) \exp[-i\beta(w_0)z + i\omega_0 t],$$

$$E_r(x, y) = E(x, y) \exp[i\beta(w_0)z + i\omega_0 t] \Phi(z, t),$$

where $\omega_0$ is the central angular frequency, $\beta(w_0)$ is the associated propagation constant, and $\Phi_1$ and $\Phi_2$ are slowly varying amplitudes. The system of equations describing degenerate four-wave mixing, in the presence of a nondepleted continuous-wave pump, is

$$[\partial/\partial z + (1/V)\partial/\partial t - (i/2A)\partial^2/\partial t^2] \Phi_1(z, t) = -iS\Phi_1(z, t) - iP\Phi_2(z, t),$$

$$[\partial/\partial z - (1/V)\partial/\partial t + (i/2A)\partial^2/\partial t^2] \Phi_2(z, t) = iS\Phi_2(z, t) + iP\Phi_1(z, t),$$

where $V = (d\beta/da)\omega_{w_0}$ and $A = (d^2/da^2)^{-1}w_{w_0}$ represent, respectively, the group velocity and the group-velocity dispersion inside the medium, which generalizes the system of equations describing degenerate four-wave mixing in thin media (where one can put $1/V = 1/A = 0$) and in relatively thick media $^{4,5}$ ($1/A = 0$). The coefficients $S$ and $P$ are given by

$$S = 2\alpha w_0 (n_2/c)\beta^2 (\Phi_1^2 + \Phi_2^2)$$

and

$$P = 2\alpha w_0 (n_2/c)\Phi_1 \Phi_2,$$

where $\alpha$ is the central angular frequency, $\beta(w_0)$ is the associated propagation constant, and $\Phi_1$ and $\Phi_2$ are slowly varying amplitudes. The system of equations describing degenerate four-wave mixing, in the presence of a nondepleted continuous-wave pump, is

$$[\partial/\partial z + (1/V)\partial/\partial t - (i/2A)\partial^2/\partial t^2] \Phi_1(z, t) = -iS\Phi_1(z, t) - iP\Phi_2(z, t),$$

$$[\partial/\partial z - (1/V)\partial/\partial t + (i/2A)\partial^2/\partial t^2] \Phi_2(z, t) = iS\Phi_2(z, t) + iP\Phi_1(z, t),$$

where $V = (d\beta/da)\omega_{w_0}$ and $A = (d^2/da^2)^{-1}w_{w_0}$ represent, respectively, the group velocity and the group-velocity dispersion inside the medium, which generalizes the system of equations describing degenerate four-wave mixing in thin media (where one can put $1/V = 1/A = 0$) and in relatively thick media $^{4,5}$ ($1/A = 0$). The coefficients $S$ and $P$ are given by

$$S = 2\alpha w_0 (n_2/c)\beta^2 (\Phi_1^2 + \Phi_2^2)$$

and

$$P = 2\alpha w_0 (n_2/c)\Phi_1 \Phi_2,$$

where $\alpha$ is the central angular frequency, $\beta(w_0)$ is the associated propagation constant, and $\Phi_1$ and $\Phi_2$ are slowly varying amplitudes. The system of equations describing degenerate four-wave mixing, in the presence of a nondepleted continuous-wave pump, is

$$\frac{\partial}{\partial z} \Phi_1(z, t) = -iS\Phi_1(z, t) - iP\Phi_2(z, t),$$

$$\frac{\partial}{\partial z} \Phi_2(z, t) = iS\Phi_2(z, t) + iP\Phi_1(z, t),$$

where $S$ and $P$ are given by

$$S = 2\alpha w_0 (n_2/c)\beta^2 (\Phi_1^2 + \Phi_2^2)$$

and

$$P = 2\alpha w_0 (n_2/c)\Phi_1 \Phi_2,$$
where \( n_2 \) is the nonlinear refractive index of the medium and \( \alpha \) is a suitable superposition integral between the normalized intensities of the pump and signal modes. If \( P \) does not depend on \( z \) [which can be shown to hold true whenever \( |E_p(+)(z = 0)|^2 = |E_p(-)(z = 0)|^2 \)], the system of Eqs. (3) can be solved exactly by employing the standard normal-mode expansion, that is, by looking for a solution of the kind

\[
\Phi_i(z, t) = \tilde{\Phi}_i(\omega) \exp[ik(\omega)z - i\omega t],
\]

\[
\Phi_i^*(z, t) = \tilde{\Phi}_i^*(\omega) \exp[ik(\omega)z + i\omega t].
\]

By proceeding in this way, we obtain

\[
\tilde{\Phi}_i(z, t) = e^{-iSz} \times \int_{-\infty}^{+\infty} d\omega G(\omega) \exp[-i(\omega^2 z/2A) - i\omega t] \times i(\omega/V) \sin[f(\omega)(z - L)] + f(\omega) \cos[f(\omega)(z - L)] \over f(\omega) \cos[f(\omega)L] - (i\omega/V) \sin[f(\omega)L]
\]

\[
\tilde{\Phi}_i^*(z, t) = \frac{1}{3!} \frac{\partial}{\partial^3 t} + i \frac{\partial}{4! \partial^4 t} \mp \ldots
\]

(7)

The upper and the lower signs applying, respectively, to the first and the second equations. It turns out, however, that only the terms containing odd derivatives with respect to time are capable of affecting the complex reflectivity \( R(\omega) \); in other words, if one could neglect all these terms [including \((1/V)\partial/\partial t\)], degenerate four-wave mixing would give rise to an exact time-reversed replica of the incident signal.

On physical grounds, the lack of influence of even-order group dispersion on complex reflectivity can be associated with the property of four-wave mixing of providing a time-reversed replica of the signal. In fact, even-order dispersion corresponds, in the time domain, to terms that are invariant in the exchange \( t \rightarrow -t \).
