anisotropic and nonlinear acoustic effects might also be directly studied.

3) Information regarding the pressure or density modulation of the ground-state and excited-state absorption in the crystal.

The amount of information simultaneously obtained from measurements such as these, concerning both molecular and crystalline properties, is sizable. We hope this process can be naturally extended to other materials as well, providing a unified understanding of their properties.

Acknowledgment

Earlier work on the transient grating experiments was supported by the Joint Services Electronics Program at Stanford University and by the National Science Foundation. This work grew out of studies of energy transport in pentacene carried out in collaboration with Prof. M. Fayer and D. Dlott of the Stanford Chemistry Department, and we appreciate the use of molecular crystal samples provided by them.
